

NAMS AOPS-COPD II: IN VITRO ASSESSMENT OF MUCUS HYPERSECRETION WITH QUANTITATIVE AOP MODELING (COMBINATION OF 3D IN VITRO MODEL AND MATHEMATICAL MODELING FOR RISK ESTIMATION)

Shigeaki Ito, PhD

Japan Tobacco inc.,

R&D group, Scientific Product Assessment Center

Outline

- NAMs for disease risk assessment
- AOP-based in vitro testing
- Quantitative AOP modeling
- In vitro dose vs in vivo dose?
- Gaps between NAMs and RW

NAMs for disease assessment

NAMs for disease risk assessment

For future replacement of animal testing

Disease risk assessment with animal testing

Animal disease models

- Species difference
 - Low predictivity of human outcomes
- Needs for animal welfare (3Rs)
 - Replace
 - Reduce
 - Refine

with NAMs (?)

in vitro human cell cultures

- High content screening
- 3D models
- Organ(s) on chip
- ... etc.

in silico (computational) tools

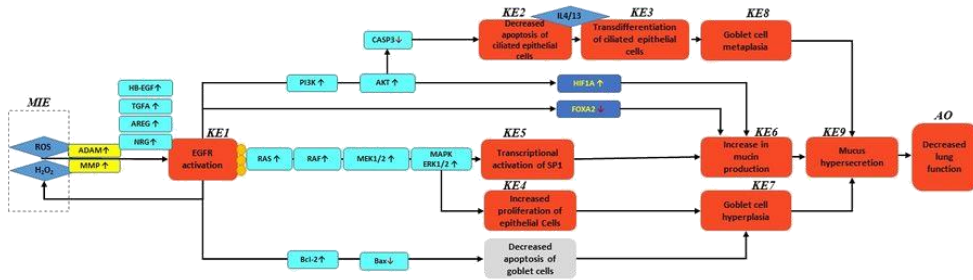

- (Q)SAR
- Read Across
- Mathematical models
- Machine learning
- ...etc.

- Use of human cell cultures
- Combination with computational tools
- Still challenging due to
 - Complexity of living system
 - Human relevant in vitro system?
 - Complexity of disease onset process
 - Adverse outcome pathway (AOP)?

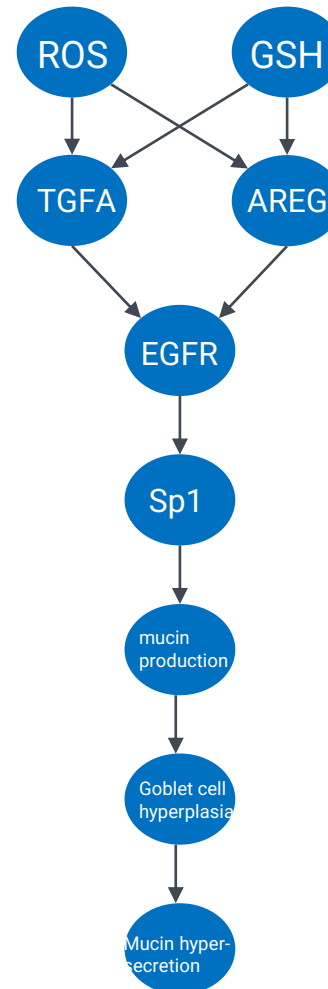

NAMs for disease risk assessment

AOP for lung function decrease (AOP148)

Original structure of AOP 148

AOP 148 for this study

Oxidative stress (MIEs)

Signal transduction
(KEs observable from **acute phase**)

Changes in phenotype
(KEs observable in **chronic phase**,
not inducible by single exposure)

Adverse Outcome
(tentative setting)

- Originally submitted to AOP-wiki by PMI and BAT.
- ROS (MIE) eventually leads to “Decreased lung function” (AO).
- We modified the AOP structure, as some of the KEs were difficult to build as in vitro assay.

NAMs for disease risk assessment

- in vitro 3D-cultured bronchial epithelial cells

3D-cultured human bronchial epithelial cells (HBEC);

- ✓ are relevant with actual human bronchial tissue structure and cell types.
- ✓ recapitulate muco-ciliary clearance.
- ✓ are inducible of disease-state by interleukin- 4 /13 treatment.
- ✓ are capable of repeated exposure study.

NAMs for disease risk assessment

Immune cell co-culture system to induce disease-state

<https://doi.org/10.1172/JCI27690>.

IL-4 and IL-13 are responsible for the induction of goblet cells. Epithelial cells are not the source of such cytokines.

Immune cells, as a source of the cytokines, are introduced to the culture system.

Mono-culture failed to induce disease-state

Co-culture system was able to induce disease-state

In Vitro Testing

Study design and results

Experimental design

Cells: 3D-bronchial epithelial cells with immune cells

Donors: 6 donors

Replicate: 3 insert/dose/donor

Test product: 1R6F reference cigarette

Exposure apparatus: Vitrocell® 24/48

Dose: 0, 1.25, 1.8, 3.3 $\mu\text{g}/\text{mL}$ Nic.equivalent conc.

Exposure repetition: 6 (Mon, Wed, Fri, 2 wks)

Sampling and harvest: 1 hour post exposure

Endpoints: ROS, GSH(MIEs), AREG and TGF α (EGFR ligands), EGFR activation (KE1), SP1 activation(KE2), Mucus production (KE3), Goblet cell meta/hyperplasia (KE4), Mucus hypersecretion (AO) __ total 9 endpoints

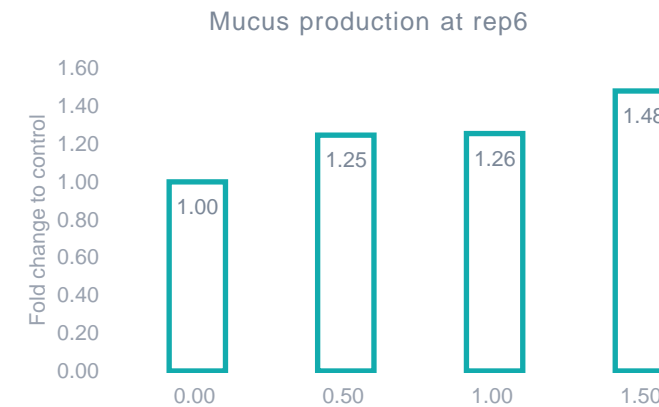

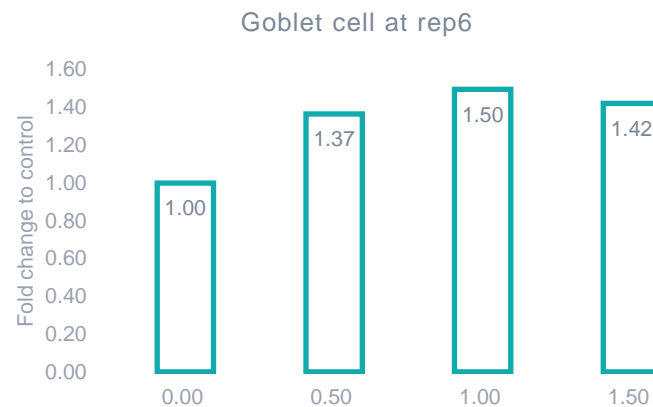

[In vitro inhalation exposure module for 24 well inserts \(vitrocell.com\)](http://vitrocell.com)

In vitro test result – acute endpoints all donor mean at exposure repetition 6

Acute-phase KEs are activated by cigarette smoke exposure

In vitro test –chronic endpoints all donor mean at exposure repetition 6

Mucin hypersecretion was significantly induced by repeated exposure of cigarette smoke.

Increase of Goblet cells
(confocal IHC, 300 μm x 300 μm , example image)

Manuscript in prep.

Mucus hypersecretion was accelerated by exposure repetition

Effects of chronic exposure to cigarette smoke could be well reproduced.

Manuscript in prep.

Testing with multiple donors could reflect individual variability?

Manuscript in prep.

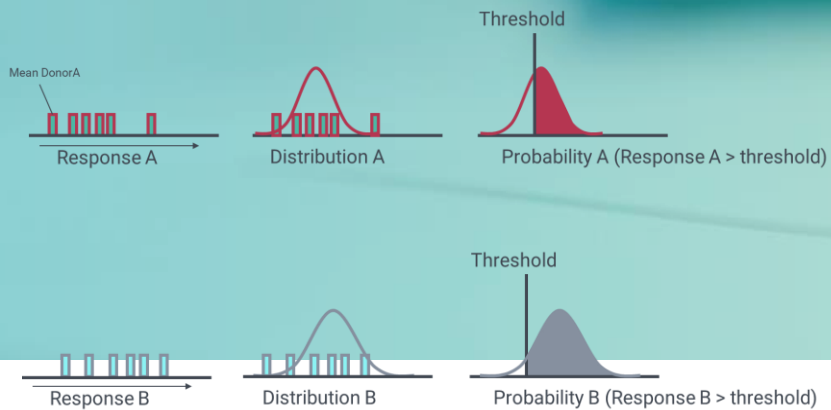

Induction of mucin hypersecretion highly varied across donors

may reflect real world situation? (e.g., not all smokers contract smoking related diseases)

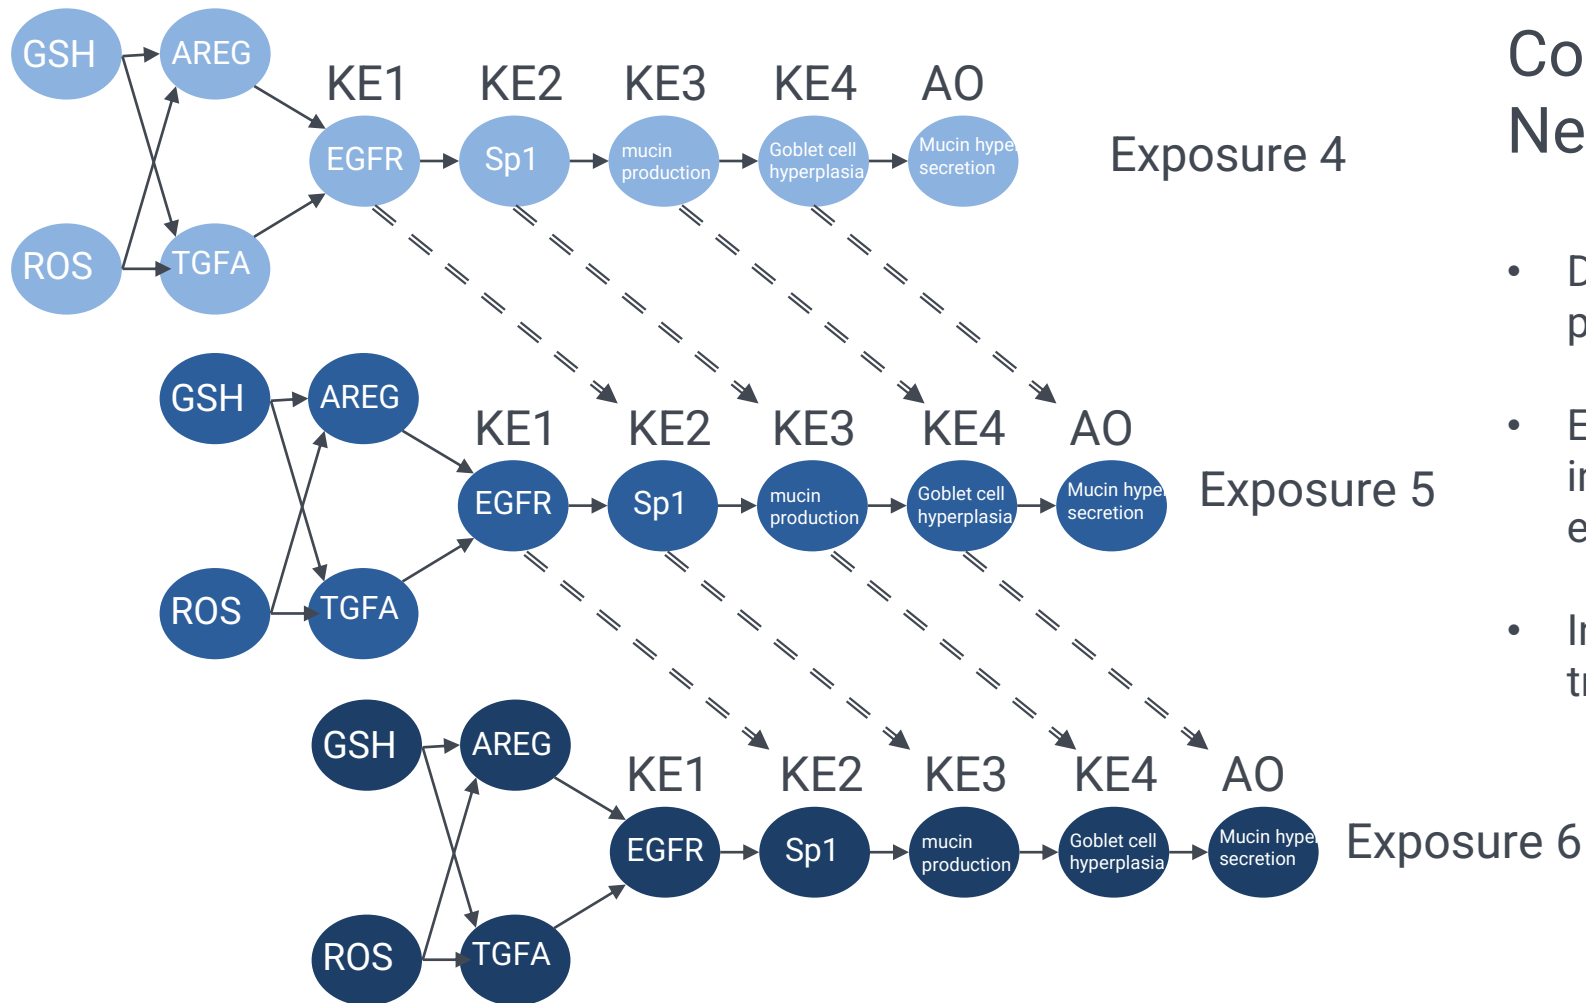

QUANTITATIVE AOP

Probabilistic modeling for disease risk assessment

$$P(B|A) = \frac{\text{Yellow Circle}}{\text{Red Circle}}$$

Transform Mean and SD of in vitro test results into Conditional transition probability

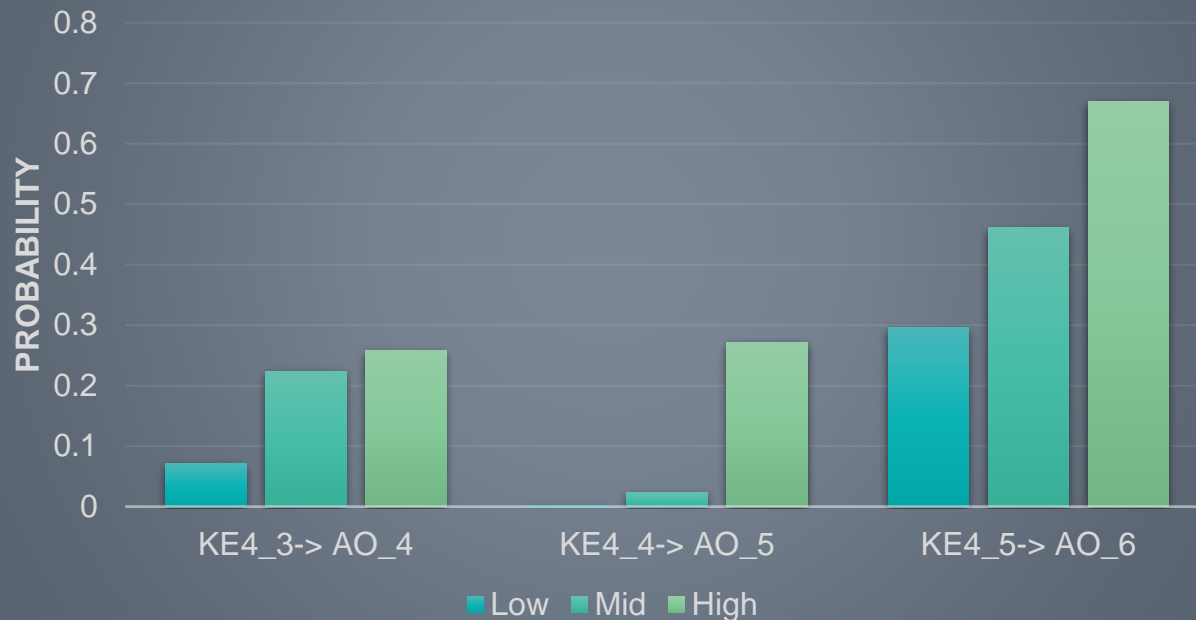

Concept of Dynamic Bayesian Network (DBN) model

- DBN model is able to capture the influence of previous exposure on the next.
- E.g. the result at exposure repetition 1 influences the probability calculation at exposure repetition 2.
- Incidence of AO is therefore calculated as transition (and conditional) probability.

AO probability is likely to be higher in the later stage exposure repetition

Manuscript in prep.

Transitional probability
($AO > \text{cutoff} | KE4 > \text{cutoff}$)

Dose dependent and mostly time-dependent increase in the probability of AO occurrence.

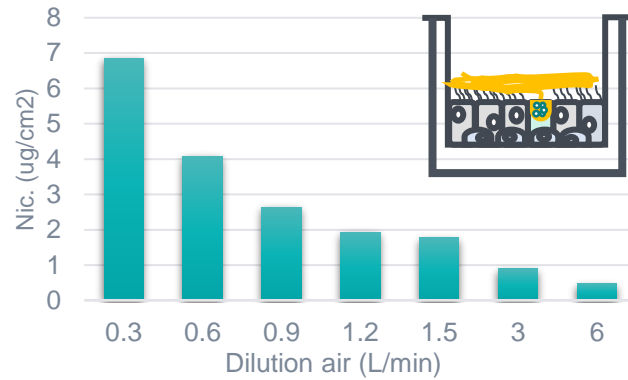

Relative risk assessment can be performed if RRP data is available with the same experimental setup.

Probability depends on:

AOP structure / In vitro data / cutoff setting/ Selected donors*

(probability in the left graph was calculated by average of random pickup of 4 out of 6 donors)

In Vitro Dose vs In Vivo Dose ?

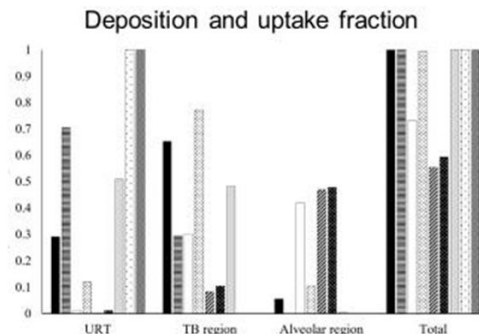

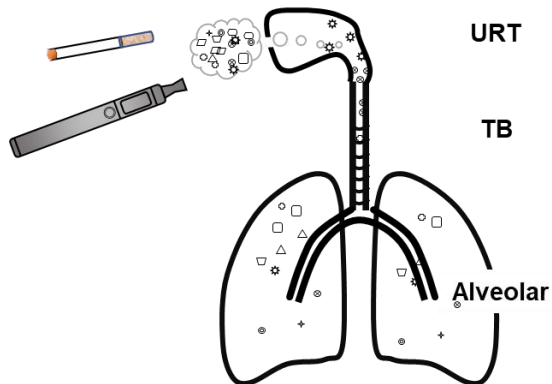

Dosimetry in in vitro test conditions approx.

0.5~1.5 $\mu\text{g Nic.} / \text{cm}^2$
per day

Deposition model

Manuscript under review

Predicted deposition in TB region

1.5 $\mu\text{g Nic.} / \text{cm}^2 / \text{day}$

in case of 1 pk (20 cigs) /day of 10 mg Tar cigarette

Gaps between Real world and NAMs.

Real world

NAMs (current study)

| | | |
|---------------------------|----------------------------|----------------------------------|
| Site of disease onset | Trachea, Bronchi, Alveolar | Bronchi |
| Number of Cell type | > 5 | 2 |
| Duration of disease onset | > Decades | > 2 weeks |
| Subjects | Population-wide | Limited donors (6 in this study) |

Should we completely fill the gaps in NAMs? OR
Gain the predictive accuracy with limited dataset?

Summary

- AOP-based *in vitro* assay system for disease risk assessment was developed.
 - Repeated exposure of whole cigarette smoke induced mucus hypersecretion.
- Bayesian network modeling of *in vitro* test results were performed.
 - Causal chain of AOP and time series of repeated exposure were integrated.
 - *in vitro* test results (mean and SD) were converted into probability of AO occurrence.

Link to real world situation should be investigated further.

Thank you for your attention!!
