Background

Since the late 1960s, a number of national and international standards (FTC, ISO, TIOJ, DIN, CORESTA) have been developed around the world for testing cigarettes by machine smoking to determine ‘tar’¹, nicotine and carbon monoxide² yields (1 - 21).

These test methods share a common purpose: to provide a basis for comparing mainstream smoke yields from different cigarettes when those yields are generated with standardized testing conditions. While the standards differ in some respects, one element that has been common to each has been the puffing regimen (i.e., the puff volume, puff duration and puff frequency) applied to the cigarette during machine smoking. Cigarettes are smoked to a fixed final butt length during which the smoking machine applies a 35 cubic centimeter puff of 2 second duration once every 60 seconds. Cigarettes are smoked as manufactured without alteration. Substantial time, effort and financial resource have been committed by industry, government and commercial laboratories to ensure each standard is consistently applied. When practiced according to specifications, each individual standard has provided a reliable and robust system for the relative ranking of cigarette smoke yields.

In the mid- to late-1990s, U.S. and Canadian authorities initiated efforts to identify one or more machine-smoking regimens that represent the way in which people smoke cigarettes, thus departing from the historical purpose associated with machine-based measurements (22 - 24). Despite the technical limitations of such a concept, new requirements for machine-smoking cigarettes have emerged in two U.S. jurisdictions, Massachusetts and Texas (25, 26), and in Canada, both provincially in British Columbia and federally (27 - 29). Concomitantly, new smoking machine hardware designed for flexible application across a range of possible smoking regimens has been introduced commercially in response to such regulations.

Recently, new regulations that require testing of numerous individual smoke constituents reported to be associated with the risks of cigarette smoking have also been introduced in some countries (27 - 30). More broadly, the WHO Framework Convention on Tobacco Control mandates that Parties to the Convention will “propose guidelines for testing and measuring the contents and emissions of tobacco products, and for the regulation of these contents and emissions” (31). Several research studies have been reported that describe individual smoke constituent yields for cigarettes sold in specific geographical regions (32 - 36). A principal challenge and potential limitation of such studies is the current lack of standardized methodology for measuring most individual smoke constituents. Further, where analytical standards do exist, method validation through interlaboratory collaborative study has historically focused on a single machine puffing regimen as the intended scope of application.

¹ The designations ‘tar’ and NFDPM will be used interchangeably to denote nicotine-free dry particulate matter.

² Carbon monoxide will frequently be referred to as CO in the text.

Task Force Mandate

The Alternative Smoking Regimes (ASR) Task Force was established by the CORESTA Scientific Commission in 2000. The task force was charged with developing “correlation models for smoke yields between ISO and representative alternative smoking regimes”. The overall charge was further divided into sub-parts: “In the first instance the models will address ‘tar’, nicotine and CO. This will be followed by benchmarking the yields of specified smoke constituents from international products (smoke constituents to be specified by the Scientific Commission).”

Participating Laboratories and Chronology of Task Force Meetings

A summary of participating laboratories and principal investigators is found in Appendix 1. A chronology of the task force meetings conducted is also included in the appendix. The task force convenors wish to acknowledge the excellent contributions of each principal investigator and their colleagues without which the work of the task force could not have been completed.

Task Force Findings

The ASR task force has addressed the first objective, the development of correlation models relating ‘tar’, nicotine and CO yields between ISO and representative alternative smoking regimes, in two study phases. In the first phase, a pilot study (ring trial) was conducted to evaluate mainstream smoke ‘tar’, nicotine and carbon monoxide yields for a limited number of cigarette brands sold in Europe. In the second phase, the alternative smoking regime capabilities established by participating laboratories in the Phase 1 study were applied to a substantially greater number of cigarette brands that represented a more global perspective. Approximately ninety brands sold in markets around the world were tested.

Before beginning the pilot study (ring trial) it was necessary to identify “representative alternative smoking regimes” for investigation in the work. Experiments which alter machine puffing parameters or artificially block cigarette ventilation holes to study the effect on mainstream smoke yields have been conducted for many years and for many different reasons (37 - 46). As such, the relative contribution of each puffing parameter (i.e., puff volume, puff frequency, puff duration) and of intentional filter vent blocking to machine-generated smoke yields is well understood. Increases in puff volume, decreases in the time between puffs and intentional blocking of filter ventilation each produces significant increases in mainstream smoke yield. Changes in puff duration have minimal effect on mainstream smoke yields. However, while research studies employing alternative smoking regimes have been conducted for many years, no consensus view regarding an appropriate alternative smoking regime(s) is found in the scientific literature and there has been no consistency in alternative smoking regimes recently introduced in regulation (47).

After considering the scope of past research studies, the capabilities of existing smoking machine hardware and the task force objective, the ASR task force membership developed a consensus opinion regarding smoking regimes for study. A guiding principle during the discussion was the desire to achieve a range for three smoking regime parameters: puff volume, puff frequency and intentional vent blocking. It was decided that the parameters would not be varied independently, but rather in combination. Smoking regimes identified for testing by the ASR task force are summarized in Table 1. In addition to providing a range of puff volume settings, puff frequency settings and vent blocking conditions, the regimes identified are currently mandated as regulatory standards. Regime #1 is specified in the ISO standard method for machine smoking of cigarettes, regime #2 is mandated by the Commonwealth of Massachusetts and regime #3 is required in Canada.

Table 1. Smoking Regimes Studied by the ASR Task Force

Smoking Regime	Puff Volume (cc)	Puff Frequency* (s)	Puff Duration (s)	Vent Blocking (%)	Description
1	35	60	2	0	ISO Standard
2	45	30	2	50	Massachusetts “Average”
3	55	30	2	100	Canada “Intense”
* Time from the start of one puff to the start of the next puff.					

Objective #1 Findings. Each cigarette was tested according to the three smoking regimes to determine NFDPM, nicotine and CO yields. Subsequently, regression analysis employing a linear model was applied to mainstream smoke yield data from ~ 90 cigarette brands to explore the relationships between smoking regimens for NFDPM, nicotine and CO. Key findings include:

1. A set of generally applicable functional relationships between ISO (Regime #1) ‘tar’, nicotine and CO yields and Regime #2 ‘tar’, nicotine and CO yields was observed based on all cigarettes studied.
2. A set of generally applicable functional relationships between ISO (Regime #1) ‘tar’ and nicotine yields and Regime #3 ‘tar’ and nicotine yields was observed based on all cigarettes studied.
3. An “adequate” functional relationship was not observed between ISO (Regime #1) CO yields and Regime #3 CO yields based on the cigarettes studied.
4. Correlations between Regime #2 and Regime #1 smoke yields were generally “stronger” than correlations between Regime #3 and Regime #1 smoke yields.

(This finding is not surprising, given that Regime #3 eliminates one cigarette design feature, i.e., filter ventilation. With one design feature eliminated, the balance between the remaining cigarette design features (e.g., the filter, paper, blend) is altered, in some instances substantially so.)

The quality of the functional relationships established when results for all brands studied served as the basis for regression analysis was assessed by comparing yield values predicted from the functional relationships with measured yield values. Findings include:

1. A difference of 3 mg, or less, was observed between Regime #2 NFDPM yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
2. A difference of 3 mg, or less, was observed between Regime #3 NFDPM yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. A difference of 5 mg, or less, was observed for more than 90% of the brands tested.
3. A difference of 0.3 mg, or less, was observed between Regime #2 nicotine yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
4. A difference of 0.3 mg, or less, was observed between Regime #3 nicotine yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. A difference of 0.5 mg, or less, was observed for more than 90% of the brands tested.
5. A difference of 3 mg, or less, was observed between Regime #2 CO yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
6. A difference of 3 mg, or less, was observed between Regime #3 CO yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. A difference of 6 – 12 mg was observed for approximately 10% of the brands tested.

In addition to exploring functional relationships between smoking regimes based on all cigarettes studied, relationships based upon a subset of the cigarette brands studied were explored. Key findings when a subset of the total cigarette brands was studied include:

1. When relationships were explored based on a specific cigarette design feature (i.e., tobacco blend), significant additional variation was explained by individual blend group models (i.e., American, Flue-cured and Dark) compared to a single grand model fit to all cigarettes tested.
2. When relationships were explored based on a specific cigarette design feature (i.e., tobacco blend), distinct functional relationships between ISO (Regime #1) nicotine and Regime #2 or Regime #3 nicotine were observed for some blends.
3. When relationships were explored based on a specific cigarette design feature (i.e., tobacco blend), a tendency toward distinct functional relationships between ISO (Regime #1) NFDPM and Regime #2 or Regime #3 NFDPM were observed for some blends.

4. When relationships were explored based on a specific cigarette design feature (i.e., tobacco blend), similar functional relationships between ISO (Regime #1) CO and either Regime #2 or Regime #3 CO were observed for different blends.
5. When relationships were explored based on the “regional product groups” designated for the study, e.g., “European Flue Cured,” significant additional variation was explained by individual product group models compared to a single grand model fit to all cigarettes tested.
6. When relationships were explored based on the “regional product groups” designated for the study, e.g., “European Flue Cured,” distinct functional relationships between ISO (Regime #1) NFDPM and either Regime #2 or Regime #3 NFDPM were observed for different product groups.
7. When relationships were explored based on the “regional product groups” designated for the study, e.g., “European Flue Cured,” distinct functional relationships between ISO (Regime #1) nicotine and either Regime #2 or Regime #3 nicotine were observed for different product groups.
8. When relationships were explored based on the “regional product groups” designated for the study, e.g., “European Flue Cured,” distinct functional relationships between ISO (Regime #1) CO and either Regime #2 or Regime #3 CO were observed for different product groups.

Beyond developing correlation models for smoke yields between ISO and representative alternative smoking regimes, testing conducted to address Task Force Objective #1 provided an opportunity to compare and assess different types of smoking machine hardware and to investigate potential approaches for data normalization to correct for interlaboratory biases (interlaboratory biases are expected due to a lack of standardized, validated testing methods for Regime #2 and Regime #3). Studies to address the first task force objective employed five different smoking machine designs, two rotary smoking machine designs and three linear smoking machine designs. A number of cigarette brands were tested in all laboratories (twelve brands in the Phase 1 study, three brands in the Phase 2 study), providing a means to (a) compare yields obtained with different smoking machine hardware, (b) estimate repeatability standard deviation (s_r) and reproducibility standard deviation (s_R), and (c) explore potential data adjustments intended to correct for interlaboratory variability due to a lack of standardized, validated testing methods. Findings include:

1. Differences in mean smoke yields were observed for the five smoking machine types applied in the study. Smoking machine designs with a longer history of use under standard ISO conditions yielded generally similar results with smoking regimes #2 and #3, with minimal distinction between linear and rotary designs. However, recently introduced linear smoking machine designs produced results that were frequently biased either high or low compared to smoking machine designs with a longer history of use, with no consistent bias direction for the three smoking regimes studied.
2. Repeatability standard deviation (s_r), an estimate of variability among replicates run under controlled conditions in the same laboratory, and reproducibility standard deviation (s_R), an estimate of variability among replicates run at different

laboratories, were determined for “tar,” nicotine and CO yield measurements according to ISO 5725-2 based on Phase 1 study results. Standard deviations were found to generally increase with mean levels. Therefore, functional relationships relating repeatability and reproducibility standard deviations to the sample mean level were developed by combining results from all smoking regimes. Repeatability and reproducibility standard deviations determined for three brands tested in the Phase 2 study were in general agreement with values observed in the Phase 1 study.

(While analyses conducted according to ISO 5725-2 suggest that, as expected, absolute variability (i.e., standard deviations) will increase with increasing mean values; this finding does not fully describe the data set developed by the ASR task force. Analysis of the data set conducted by Mr. Steve Purkis (not included in this report) suggests that in addition to a general increase in variability with increasing mean values, variability will increase for a given value (e.g., a given NFDPM value) when the yield is produced with a more intense smoking regime. Therefore, a greater standard deviation would be expected for a 15 mg NFDPM yield produced with smoking regime 3 than with smoking regime 1. Whatever the fundamental cause of the observed interaction between yield variability and smoking regime, the observation has clear regulatory implications. Any new ISO standard based on more intensive smoking regimes and any new regulatory ceilings established for product yields will have to investigate and understand differences in variability associated with interactions between analyte and smoking regime.)

3. Data adjustment to correct for interlaboratory variability due to a lack of standardized, validated testing methods was possible. Linear models were fitted relating the yields of three control cigarettes tested in each laboratory to the grand means observed for all laboratories in Phase 2. Models were fitted for control cigarette yields for all three smoking regimes combined and for each smoking regime separately. Adjustment of individual laboratory means based on application of either model (i.e., means observed at each laboratory were adjusted by subtracting the intercept and dividing by the slope of the model fit for that laboratory) reduced unexplained interlaboratory variation, making values at different laboratories more consistent. Adjustment of laboratory means based on individual smoking regimes eliminated the greatest degree of interlaboratory bias.

Objective #2 Status. Significant potential difficulties are faced when benchmarking smoke constituents other than ‘tar’, nicotine and CO, due to a lack of recognized international test methods. Currently, laboratories use their own methodology when testing to determine individual smoke constituents and substantial differences exist between test results from different laboratories (48). While the CORESTA Special Analytes task force is currently charged with collaborative evaluation of methodology for the measurement of several selected smoke constituents, the work of the task force has focused on a single machine puffing regimen (ISO) as the intended scope of application.

Given these factors, the ASR task force requested guidance from the Scientific Commission on the value of generating data without standardized, validated test methods. The ASR Task Force also proposed an initial review of existing benchmarking studies to assess the correlations found. The Scientific Commission agreed that the task force should in the first instance review the literature to identify gaps in the current knowledge base.

Review of the literature confirms that ASR task force Objective #2, “... This will be followed by benchmarking the yields of specified smoke constituents from international products (smoke constituents to be specified by the Scientific Commission),” has been achieved to a substantial extent, independent of the ASR task force. Numerous studies (32 – 36, 49, 50) have been conducted in recent years that determine the yields of individual smoke constituents (i.e., typically, “Hoffmann analytes”). The studies have included cigarette brands from several different global markets and, in some instances, have produced constituent smoke yield data using alternative smoking regimes. While in the absence of standardized, validated test methods the results of such studies cannot be viewed as “unequivocally accurate,” studies conducted in a single laboratory do provide a reasonable basis for product comparison within the study.

Phase 1 Study

The Phase 1 (pilot) study provided a first opportunity for many of the participating laboratories to determine smoke yields when cigarettes are smoked in a non-standard manner (i.e., a smoking regime other than the ISO regime), in addition to providing initial insight into the general feasibility of achieving objective 1. Before beginning the pilot study, many participating laboratories had to modify smoking machine puffing capabilities and make other adjustments to analytical methods for the determination of nicotine, water and carbon monoxide. After implementing smoking and analysis capabilities consistent with the requirements of the pilot study protocol, participating laboratories conducted a pre-test with a Kentucky reference cigarette as a final capability and viability check.

Protocol. The Phase 1 study protocol (Appendix 2) was developed with intent to balance the practical scope of the study (i.e., a study that could be completed in a reasonable period of time) with scientific robustness (numbers of ports per smoking regime, replications, etc.). The pilot study protocol was developed to test twelve cigarette samples (ten commercial brands and two reference cigarettes) using the three puffing regimens. Each participating laboratory tested all cigarette samples. The three regimes specified for study represent a range of puff volume, puff frequency and vent-blocking conditions as summarized in Table 1. Cigarette brands specified for testing (Table 2) were selected based on multiple criteria. Brands selected for testing in the pilot study represented: (a) multiple cigarette manufacturers, (b) the range of NFDPM yields found in the European market at the time of the study (ISO NFDPM yields from 1 to 12 mg/cig) and (c) typical product designs. In addition to the smoking regimes and cigarette brands

prescribed for testing, the pilot study protocol provided specific run orders for linear and rotary smoking machines, as well as electronic templates for reporting all study results.

Table 2. Brands Selected for Testing in the Phase 1 Study

Sample code	Sample Description	NFDPM level (mg/cig.)	Butt length (mm)	Circumference (mm)
A	Manufacturer A	12	29	24.7
B	Manufacturer B	12	29	24.8
C	Manufacturer C	10	23	26.7

I	Manufacturer B	3	39	24.6
J	Manufacturer B	1	35	24.8
K	Kentucky Reference 1R4F	9	35	25.0
L	CORESTA Approved Monitor CM3	15~16	32	24.8

Statistical Analysis. Statistical analysis techniques were applied to Phase 1 test results with three objectives:

1. To determine the test method capability for each type of smoking machine applied by participating laboratories,
2. To compare mean performance of the different smoking machines, and
3. To develop functional relationships between the two alternative smoking regimes (Regimes #2 and #3) and the ISO standard smoking regime (Regime #1) for NFDPM, nicotine and carbon monoxide.

Statistical analysis for the first objective generally followed procedures described in ISO standard 5725-2 (51) which describes a standard approach for detection of outlier values, estimation of sample mean values, and estimation of repeatability and reproducibility standard deviations for each sample.

For these purposes, the combination of a particular smoking machine used to test a particular cigarette brand style with a particular smoking regime was treated as a test

sample. The smoking machine categories used were the RM20³, RM200, SM400, and ASM500. The KC Automation 10-port smoking machine was used by a single laboratory. While values for the mean and repeatability could be obtained for data from the single laboratory that used the KC Automation 10-port smoking machine, no estimate of reproducibility standard deviation could be obtained. As such, there could be no confidence that values so obtained would be typical of those produced by other laboratories using the machine. Thus, a fifth “smoking machine” category was defined by combining the SM400 and the KC Automation smoking machine data and analysis was applied to the combined smoking machine category to determine if the KC Automation machine performance was consistent with the SM400 smoking machines.

While many procedures have been developed to identify outliers in a data set, ISO 5725-2 specifically recommends the use of Mandel charts for visualization of outlier laboratories across samples, and Cochran’s test and Grubbs’ test for identification of outlier laboratories for individual test samples. Mandel charts present normalized mean and sample standard deviation values for all laboratories for all test samples, with lines to indicate statistically significant outlier laboratories. Based on these charts, all data from a laboratory may be excluded if the analyst judges that a laboratory is consistently different from the others, although the standard does not specify rules for making this determination.

For Phase 1, these charts were produced separately for yields of the twelve cigarette brands with each smoking regimen using either linear smoking machines or rotary smoking machines. They were used primarily to identify outlier smoking machine ports. Individual port values for laboratories with outlier standard deviations (identified by the Mandel charts) were examined for “reasonableness” using plots of the raw data. Ports which appeared different from others at the same lab were investigated further for assignable cause. If an assignable cause was identified by the participating laboratory that generated the data (e.g., a particular port yield value was not divided by the number of cigarettes), then the values were corrected and retained. If no assignable cause was identified, the port was excluded from further statistical analysis (14 ports in total were excluded). For linear machines, the ten individual port values exhibited a wider range for some laboratories than for others. When a wider range was observed without any particular port appearing unusual, all ports were retained. With only three ports generated with rotary machines, extremely wide ranges were required to justify dropping a port (in total, two individual ports were excluded based on this criteria). All six analytical endpoints were dropped for excluded ports. In addition, all CO data from one laboratory tested with regimen 3 were excluded since the Mandel chart showed that values were unusually low for all twelve cigarettes. For these measurements, data from the other endpoints were retained.

In contrast to the absence of firm recommendations for excluding data from outlier laboratories based on Mandel charts, ISO 5725-2 clearly specifies a procedure for applying Cochran’s test (for identifying laboratories with significantly greater variability

³ RM20 is used throughout this document and generally refers more specifically to Borgwaldt smoking machine model RM20CSR.

than the other laboratories), and Grubbs' test (for identifying laboratories with means which are significantly different from the other laboratories) in sequence, with multiple iterations. For this study, Cochran's test was applied, followed by Grubb's test. With as many as six laboratories using a particular smoking machine, outlier evaluation was stopped after the exclusion of one laboratory. With only four laboratories using the ASM500, critical values for outlier laboratories are relatively extreme, such that no outlier laboratories were identified for any endpoint for any test sample. Laboratories deemed outliers by either of these tests (which required $p < 0.01$) were excluded from calculations of the mean, repeatability standard deviation, and reproducibility standard deviation per ISO 5725-2 for that test sample for that particular analytical endpoint.

Repeatability standard deviation is an estimate of variability among replicates run under controlled conditions in the same laboratory (estimated by pooling standard deviation estimates across laboratories), while reproducibility standard deviation is an estimate of variability among replicates run at different laboratories. These quantities were estimated for each sample after the exclusion of outliers, as described in ISO 5725-2. The estimation of repeatability standard deviation and reproducibility standard deviation uses a "method of moments" variance components analysis.

ISO 5725-2 provides additional procedures for developing functional relationships for relating repeatability and reproducibility standard deviations to the sample mean level, where such relationships are consistent with the data. Linear models relating variability to the mean level with and without intercepts were fitted, as well as an exponential model relating the log of variability to the log of the mean, according to ISO 5725-2. These models were fitted to mean and standard deviation estimates for all cigarettes using any of the smoking regimens for each smoking machine (36 data points for each model – 12 cigarette brand styles with 3 regimens). The three model forms were compared across smoking machines and analytical endpoints to identify the simplest model form that would provide an adequate fit in most cases.

Comparisons of mean yields for different smoking machine types were made using analysis of variance in a two-way model with cigarette brand style and test instrument, followed by post hoc pair-wise Tukey's tests to find significant differences among the smoking machines. The KC Automation smoking machine was treated as a separate smoking machine in these analyses. These analyses were performed separately for each smoking regimen for each analytical endpoint. While cigarette by smoking machine interactions were significant in some cases, machine differences were generally consistent across cigarette brand styles.

In order to examine the relationship between yields of NFDPM, nicotine and CO under alternative smoking regimes to those of the standard ISO regime, linear and quadratic regression models were fitted to the means of these analytical endpoints across all laboratories. The improvement in the error sum of squares obtained by adding the quadratic term to the model was calculated and compared to the error mean square for the linear regression model using an F test. The reduction in the error sum of squares was declared significant if the associated p-value (denoted "P Imp" in Appendix 4, Tables 4 –

9) was less than 0.05, indicating that a significant improvement in the model fit was obtained by adding the quadratic term.

All analyses were performed using SAS[®] (SAS Institute, Cary, NC) software.

Discussion of Results.

Establish Viability of Participating Laboratories. Initial inspection and review of data generated in the Phase 1 study (Appendix 3) suggested reasonable agreement between the mean values obtained by each participating laboratory. For each cigarette studied, good general agreement was found for each smoke yield measurement conducted (NFDPM, nicotine, CO). Statistical analysis of the twenty-two data sets produced in the study did not reject any complete data set as an outlier, although some individual endpoints were excluded as outliers based on either preliminary assessment with Mandel Plots (Appendix 4, Table 1) or Cochran / Grubbs outlier tests (Appendix 4, Table 2). Coefficients of variation (i.e., %RSD) based on laboratory means for the twelve cigarettes tested were typically 4 – 9 for each smoke yield measurement and smoking regime (Table 3). In addition to good interlaboratory agreement, intralaboratory precision was generally comparable for all three smoking regimes studied. The degree of interlaboratory agreement observed and the general intralaboratory precision found were most impressive given that: (1) two of the smoking regimes applied in the study had not been previously attempted by many of the participating laboratories and (2) at least five different types of smoking machine were used to conduct the pilot study. It should be noted however, that while the coefficients of variation are generally comparable for each of the smoking regimes, absolute variability is increasing from regime #1 to regime #3. It is expected that interlaboratory validation of the more intensive smoking regimes will lead to reductions in the observed absolute variability and corresponding coefficients of variation.

Table 3. Coefficients of Variation Based on Laboratory Means

Smoke Yield	Smoking Regime	Coefficient of Variation for Twenty-two Laboratory Means (Twelve Brands)		
		Average of All Brands	Minimum (Single Brand)	Maximum (Single Brand)
NFDPM	1	7.0	4.4	20.0
	2	5.9	3.7	10.9
	3	6.3	4.4	10.5
Nicotine	1	5.4	3.1	12.8
	2	4.7	3.6	5.6
	3	4.3	3.6	6.1
CO	1	9.0	7.0	13.8
	2	6.8	6.1	8.3
	3	7.2	5.9	8.0

Evaluate Accuracy. Comparison of CM3 reference cigarette yields obtained in the Phase 1 study with yield values determined in the CM3 annual smoking study provide an indication of Regime #1 accuracy. Grand means for NFDPM, nicotine, CO and puffs from the twenty-two data sets generated in Phase 1 show good agreement with CM3 values established in 2000 (Table 4). Similarly, comparison of Kentucky reference cigarette yields obtained in the Phase 1 study with the limited data available for such yields when smoking with either Regime #2 or Regime #3 also demonstrated good agreement for NFDPM, nicotine and CO yields (Tables 5 and 6). (Available Kentucky reference yield data for Regimes #2 and #3 were generated in a relatively few laboratories (four, or less) and the laboratories had varying degrees of experience with alternative smoking regimes when the data were generated).

While the results summarized in Table 4 – 6 suggest good agreement when the grand means for results from all participating laboratories are compared to historical values, it is also important to consider the extent of agreement, or difference, observed for the various smoking machine types employed in the Phase 1 study. Differences in smoke yields, if found, would potentially guide the design of a Phase 2 study, a study intended to address a broader range of cigarettes. In such a study, it would not be possible to smoke all cigarettes in each laboratory, an approach that tends to “average out” individual laboratory differences when applied.

An analysis of variance was conducted for each smoking endpoint to discern possible smoking machine differences. Differences in smoke yields were observed for the five smoking machine types used by Phase 1 participants. A post-hoc Tukey’s test (Appendix 4, Table 3) identified smoking machine types that produced equivalent yields for each smoking regime. In general for the smoking regimes studied, smoking machines with a longer history of use (i.e., SM400, RM20 and RM200) tended to produce means towards the middle of the observed range, while smoking machines designed more recently to address the emerging demand for multiple smoking regime capability often tended to the upper and lower segments of the observe yield range. It should be noted that although statistically significant differences in smoke yields were observed for different smoking machine types, the differences were not extreme. For example, the range of NFDPM yields for Regime #3 was ~ 24 – 27 mg/cig. However, based on differences observed, the range of smoking machine designs available for use will be an important consideration in planning the Phase 2 study design.

**Table 4. Comparison of Historical and Phase 1 Study
CORESTA Monitor 3 Results – Regime #1 (Standard ISO regime)**

	NFDPM (mg/cig)	Nicotine (mg/cig)	CO (mg/cig)	Puffs (per cig)
Phase 1 Study (22 Data Sets)	15.1	1.25	14.9	8.9
CM3 annual Smoking Study 2000	15.1	1.24	15.0	8.9

**Table 5. Comparison of Historical and Phase 1 Study
1R4F Results – Regime #2**

	Historical Results Average \pm 1 SD	Phase 1 Study Average \pm 1 SD
NFDPM (mg/cig)	20.4 ± 0.9	19.7 ± 1.0
Nicotine (mg/cig)	1.60 ± 0.07	1.54 ± 0.06
CO (mg/cig)	24.7 ± 1.4	24.2 ± 1.6

**Table 6. Comparison of Historical and Phase 1 Study
1R4F Results – Regime #3**

	Historical Results Average \pm 1 SD	Phase 1 Study Average \pm 1 SD
NFDPM (mg/cig)	29.7 ± 1.8	26.0 ± 1.4
Nicotine (mg/cig)	1.87 ± 0.11	1.90 ± 0.08
CO (mg/cig)	30.9 ± 2.0	31.6 ± 2.0

Evaluate Precision. Repeatability standard deviation (s_r), an estimate of variability among replicates run under controlled conditions in the same laboratory, and reproducibility standard deviation (s_R), an estimate of variability among replicates run at different laboratories, were determined for “tar,” nicotine and CO yield measurements according to ISO 5725-2 based on Phase 1 study results. Standard deviations were found to generally increase with mean levels. Therefore, functional relationships relating repeatability and reproducibility standard deviations to the sample mean level were developed by combining results from all smoking regimes (Appendix 4, Figures 1 – 15). Slope and intercept coefficients for the functions so developed (Table 7) suggest that reproducibility standard deviations are comparable for different smoking machine types, while repeatability standard deviation may be somewhat less for rotary machines in comparison to linear machines. This may be due, in part, to different numbers of cigarettes smoked per replicate.

Develop Correlation Models. The ASR task force has examined the relationships between NFDPM, nicotine and carbon monoxide yields, when yields are generated with the three smoking regimes. Regression analysis using both linear and quadratic models was applied to the grand means for each yield parameter (NFDPM, nicotine, carbon monoxide) from the 22 available data sets. Regression analysis results based on the twelve cigarettes tested support the premise that empirical correlation models for smoke yields between ISO and representative alternative smoking regimes can be developed (Figures 1 – 3, Table 8). Comparison of linear and quadratic models suggests that a quadratic model offers little, if any improvement over a linear model when correlating the smoke yields generated with different smoking regimes (Appendix 4, Tables 4 – 9). This finding was consistently observed both when reference cigarette data were included and excluded from the data set during model generation.

Data from one product (Gauloise Filter) were excluded when generating models that relate nicotine yields from alternative smoking regimes with the nicotine yield from Regime #1. Gauloise Filter data were excluded because a different relationship was observed between nicotine and NFDPM when data from the three smoking regimes studied were combined and examined (Figure 4). Gauloise Filter was the only cigarette

in the Phase 1 study with a “dark tobacco blend,” suggesting that cigarettes with different tobacco blends (e.g. flue cured, American and dark blends) may produce different functional relationships for one or more smoke yield parameters.

Table 8. Summary of Model Coefficients and r^2 Statistic for Phase 1 Study Results

Figure 1. NFDPM Functional Relationships Observed Based on Commercial Brands and Reference Cigarettes (Linear Model)

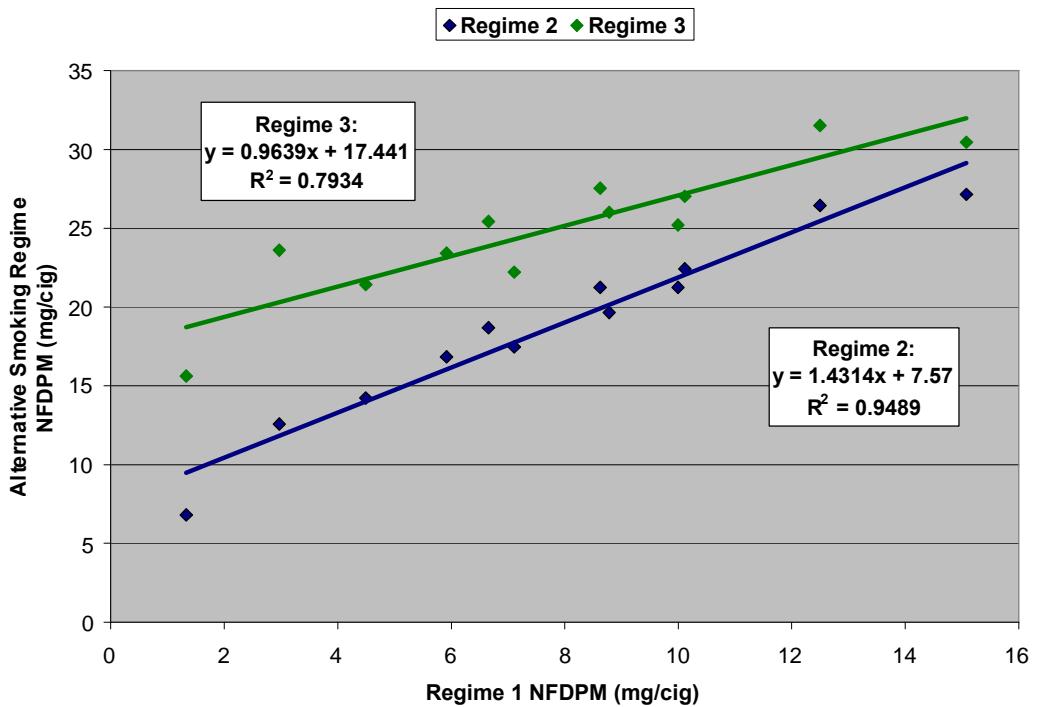

Figure 2. Nicotine Functional Relationships Observed Based on Commercial Brands and Reference Cigarettes (Linear Model)

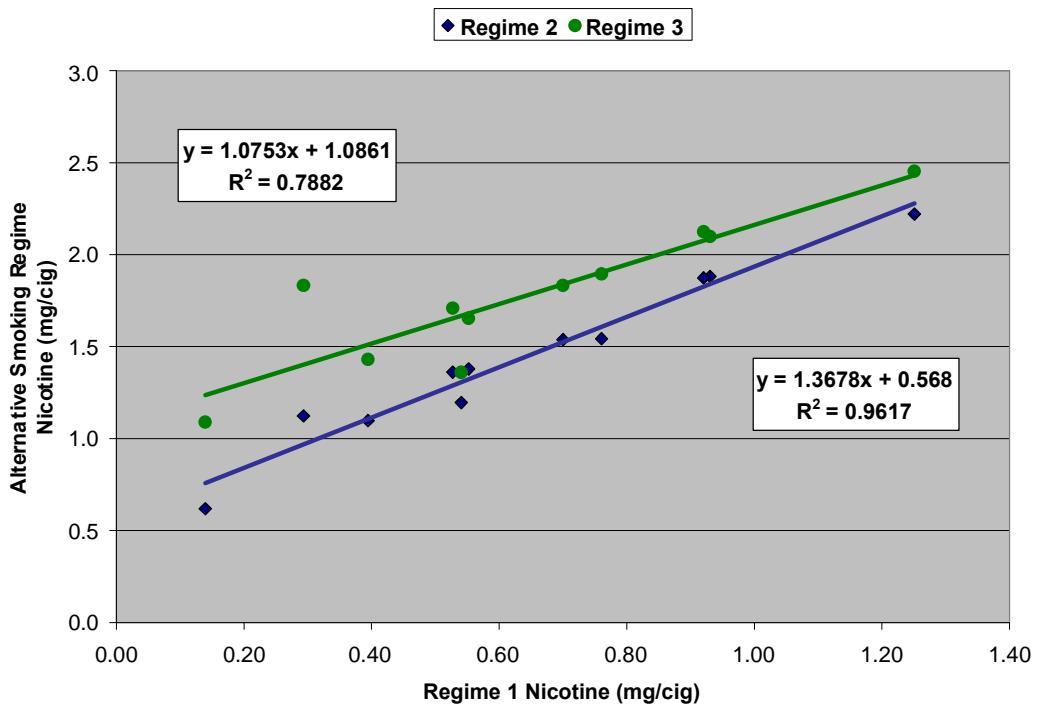

Figure 3. CO Functional Relationships Observed Based on Commercial Brands and Reference Cigarettes (Linear Model)

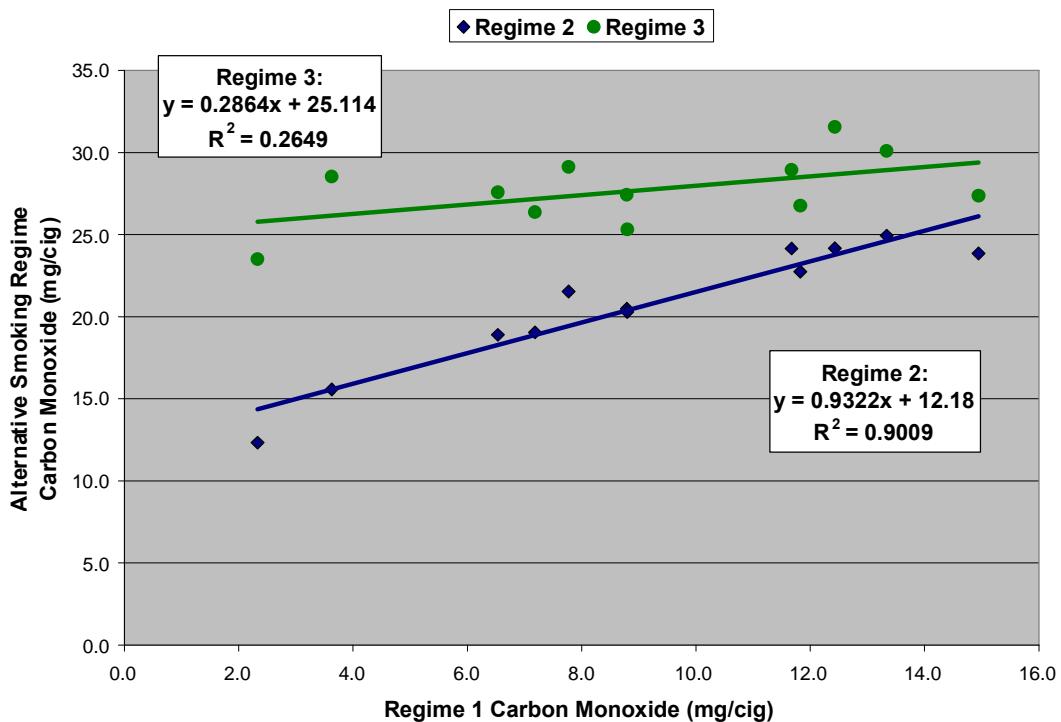

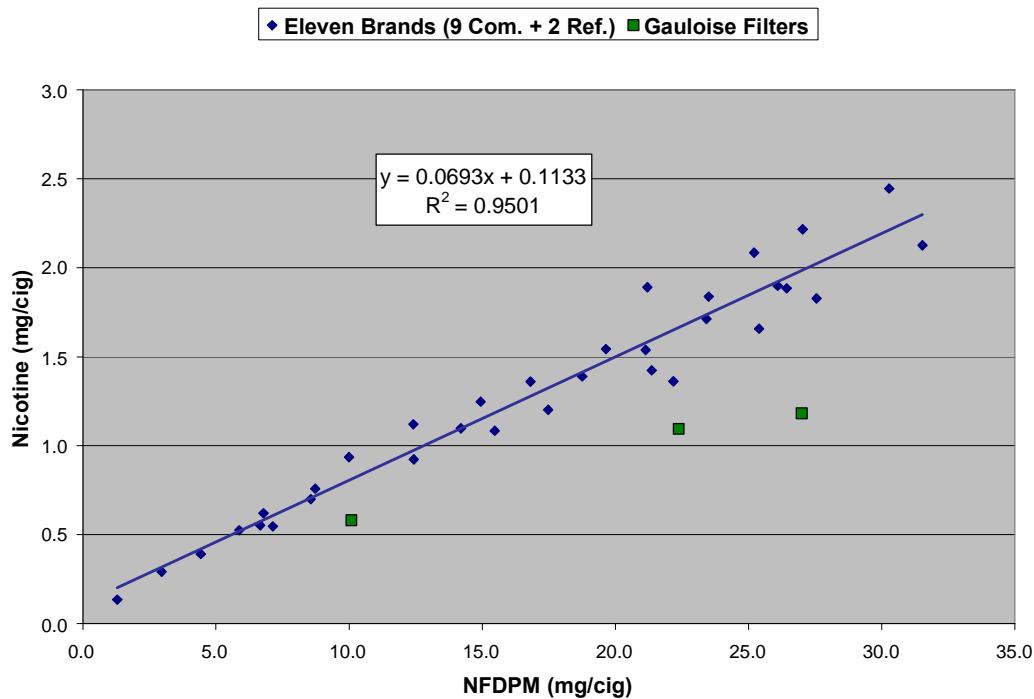

Figure 4. Relationship Observed Between Nicotine and NFDPM Yields for Gauloise Filter and Other Cigarettes

The quality of the functional relationships established in the Phase 1 study was assessed by comparing yield values predicted from the functional relationships with measured yield values (Tables 9 – 11). For functional both linear and quadratic relationships generated from commercial brands and reference cigarettes, findings for the ~264 values (i.e., 22 laboratory data sets x 12 products evaluated in each laboratory resulted in 264 values for each smoke yield parameter) include:

1. Differences of 2 mg, or less, were observed between predicted and measured Regime #2 NFDPM yields for more than 80% of the individual measurements conducted.
2. Differences of 3 mg, or less, were observed between predicted and measured Regime #3 NFDPM yields for more than 80% of the individual measurements conducted.
3. Differences of 0.2 mg, or less, were observed between predicted and measured Regime #2 nicotine yields for more than 95% of the individual measurements conducted.
4. Differences of 0.3 mg, or less, were observed between predicted and measured Regime #3 nicotine yields for approximately 90% of the individual measurements conducted.
5. Differences of 2 mg, or less, were observed between predicted and measured Regime #2 CO yields for more than 80% of the individual measurements conducted.
6. Differences of 3 mg, or less, were observed between predicted and measured Regime #3 CO yields for more than 80% of the individual measurements conducted.

Yield Modeling Based on Puff Volume, Filter Ventilation and Puff Interval. Discussion of statistical modeling techniques as a means of predicting alternative smoking regime smoke yields from a puff volume, puff interval and the cigarette filter ventilation value, rather than predicting alternative smoking regime smoke yields from the standard ISO smoking regime, was addressed during ASR task force meetings. Mr. Paul Case led the discussion based on research conducted at BAT. He has presented findings from such studies involving a statistically based central composite design at recent CORESTA meetings (52, 53) A principal advantage of such an approach is that models are obtained for a range of puff volumes, puff intervals and ventilation conditions, rather than models that correlate specific smoking conditions.

Conclusion from Phase 1 Study.

Phase 1 study results from twenty-two data sets suggest that sufficient technical capability exists within the participating laboratories to continue with a broader study to develop correlation models for smoke yields between ISO and representative alternative smoking regimes. Laboratories that participated in the Phase 1 study were able to test cigarettes with representative alternative smoking regimes that encompassed a range of puff volumes, puff frequencies and cigarette vent blocking conditions. Reasonable accuracy and precision were observed in the Phase 1 study when participating laboratories used one of five types of analytical smoking machine to smoke cigarettes with the ISO and two alternative smoking regimes. After developing sufficient technique, the study participants were able to successfully apply tape to the cigarette filter to block ventilation holes (when present) around either 50% or 100% of the cigarette circumference. Since statistically significant differences in smoke yields were observed for different smoking machine types, and while the observed differences were not extreme, consideration of potential adjustment methods to compensate for differences in smoke yields due to smoking machine type should be a key consideration for developing a plan to test a broader range of cigarettes.

Results of regression analysis based on the twelve cigarettes tested support the premise that empirical correlation models for smoke yields between ISO and representative alternative smoking regimes can be developed. Differences in smoke yields observed for one of the products tested suggests that unique correlation models may exist based on different tobacco blend or other product design features. In developing a study protocol to broaden the scope of correlation models beyond the ten European brands evaluated in the Phase 1 Study, cigarette brands representing a range of ISO “tar” yields, a variety of tobacco blends and commercial availability from many geographical regions is recommended. With such a diverse set of cigarettes, it must be recognized that: (a) a single set of generally applicable functional relationships for ‘tar’, nicotine and CO yields between ISO and representative alternative smoking regimes may be found, (b) multiple sets of functional relationships based upon specific cigarette design features (e.g., tobacco blend) may be observed or (c) a lack of adequate functional relationship(s) that correlate ‘tar’, nicotine and CO smoke yields between ISO and representative alternative smoking regimes is possible.

Phase 2 Study

Study objectives for Phase 2 of the ASR Task Force effort were (1) to apply experience and learning from the preliminary work (Phase 1 Study) to develop more robust correlation models for smoke yields between ISO and representative alternative smoking regimes based on ‘tar’, nicotine and CO; and (2) to broaden the scope of smoke yield relationships developed for ten European brands in the Phase 1 Study to include cigarette brands from many geographical regions (more global perspective).

Protocol. The Phase 2 study protocol was completed and distributed to participating laboratories in late 2002. Unlike the Phase 1 study in which all laboratories tested a single group of ten commercial products and two reference cigarettes, distinct product groups consisting of ten commercial products and three reference cigarettes were tested by designated laboratories only. Nine product groups arbitrarily identified as: Ad Hoc Group, American Blends, Canadian Brands, Dark Blends, Europe Flue Cured, European Group, Japan Domestic / Other, UK Benchmark Brands, US Brands were established for testing based on consensus of the participating laboratories and a willingness of the participating cigarette manufacturers to provide products for testing. Each product group consisted of cigarettes with a range of NFDPM yields, rod lengths, circumferences and other characteristics typical of various geographical regions represented by the product group. Cigarettes from Canada, Croatia, England, France, Germany, Indonesia, Italy, Japan and the United States were included in the various product groups. The product groupings were not constituted with the intention of ranking the “relative goodness” of different blend types or product designs, but rather with the intention of comparing a large number of cigarette brands representing a global perspective in an orderly manner.

At a minimum, each product group was tested in two laboratories, one with a linear smoking machine capability and another with rotary smoking machine capability. Some product groups were tested in as many as four laboratories. Linear smoking machines utilized by study participants included the TriCity Machines Hawktech 1000, Filtrona SM400 and Cerulean ASM516 smoking machines. Rotary smoking machines utilized by study participants included Borgwaldt RM20 and RM200 (with kit) smoking machines. The three smoking regimes applied in the Phase 2 study were identical to the smoking regimes applied in the pilot study. Puff volume, puff frequency, puff duration and vent blocking conditions for each smoking regime are summarized in Table 1.

Participating laboratories, principal investigators, smoking machine types and product group assignments for the Phase 2 study are summarized in Tables 12 and 13. The principal investigators from each laboratory and their colleagues are to be commended for the excellent efforts put forth in completing the experimental portion of the Phase 2 study. The logistics of test product distribution alone were somewhat daunting and the laboratory portion (with many accompanying data spreadsheets) was quite complex, yet excellent data was produced by all participating laboratories in a timely manner.

Table 12. Product Group Assignments for Laboratories with Linear Smoking Machine Capability

Laboratory	Principal Investigator	Machine(s)	Product Group Assignment for Phase 2 Study

Statistical Analysis. Statistical analysis techniques were applied to Phase 2 test results with three objectives:

1. To determine the test method capability for each type of smoking machine applied by participating laboratories,
2. To compare mean performance of the different smoking machines, and
3. To develop functional relationships between the two alternative smoking regimes (Regimes #2 and #3) and the ISO standard smoking regime (Regime #1) for NFDPM, nicotine and carbon monoxide.

A Dixon test for normal distribution extreme outlier replicate values was performed on individual values for each cigarette measured at each smoking regime, when applicable. Dixon tests were performed for laboratories using linear smoking machines, but not for laboratories using rotary smoking machines since these laboratories only generated three replicate values per cigarette. Subsequently, Dixon tests for normal distribution extreme outlier laboratory means were performed on laboratory means for all laboratories for the three control cigarettes (a commercial 1 mg yield cigarette, the 1R4F Kentucky reference cigarette and CORESTA monitor cigarette CM4). These were performed separately for each type of smoking machine. (Data from the laboratory using the Hawktech smoking machine were excluded from this evaluation.)

As in Phase 1, the mean, repeatability standard deviation and reproducibility standard deviations were estimated to describe the test method capability for each type of smoking machine. Since most cigarette brand styles were smoked in 2 – 4 laboratories, statistical analysis was based on the three control cigarettes common to all laboratories. However,

since only three cigarettes were tested at every laboratory, no attempt was made to develop functional relationships between the means and repeatability or reproducibility standard deviations. Rather, estimates of these quantities established from Phase 2 study data were plotted together with the models developed in Phase 1 to evaluate the extent of consistency with Phase 1 results. Since no Cochran's or Grubb's tests were used to exclude laboratories, this comparison also provides a measure of potential improvement in laboratory performance since Phase 1.

Yields for the three control cigarettes were compared among the smoking machines using analysis of variance followed by post hoc Tukey's tests to compare the smoking machines on a pair-wise basis. The Hawktech smoking machine was treated as a separate smoking machine type in these analyses. Analysis was completed for each control cigarette separately with a one-way analysis of variance on smoking machine, and also with a two-way analysis of variance on smoking machine and cigarette. As in Phase 1, while cigarette by smoking machine interactions were significant in some cases, machine differences were generally consistent across cigarette brand styles.

In order to examine the relationship between yields of NFDPM, nicotine and CO under alternative smoking regimes to those of the standard ISO regime, linear regression models were fitted to the means of these analytical endpoints for (1) the laboratories that tested each product group, (2) all laboratories and (3) laboratories that tested cigarettes with a similar tobacco blend. However, because of differences observed for different types of smoking machine in the Phase 1 study and general interlaboratory differences typically expected, normalization of mean values seemed appropriate to make values generated at different laboratories as comparable as possible. This was especially important because different laboratories smoked different cigarette product groups. For this purpose, models relating the yields of the three control cigarettes at each laboratory to the grand means observed at all laboratories were fitted. Models were fitted both for yields of the control cigarettes for all three smoking regimes combined and for each smoking regime separately. Tests were performed to see if the set of models fit separately for each regime provided statistically significant improvement in the fit (i.e., a significant reduction of unexplained variation) compared to a single model fit for all three regimes combined. Means observed at each laboratory were adjusted by subtracting the intercept and dividing by the slope of the model fit for that laboratory. This adjusted value is the grand mean value that would have produced the observed value, and thus has the effect of removing laboratory differences. Adjusted values for all cigarettes smoked at each laboratory (not just the control cigarettes) were obtained using these models.

To describe the relationship between different smoking regimes, regression models were fitted to mean values for commercially available cigarette brand styles (control cigarettes were excluded) observed at each laboratory, predicting yields when smoking with the two alternative smoking regimes (Regimes #2 and #3) from the ISO standard smoking regime (Regime #1) yields. Models were fitted for the observed means, for means adjusted using models fit to all smoking regimes (All-Adjusted) and for means adjusted using models fit separately for each smoking regime (Regime-Adjusted). Next, similar models were fitted for all laboratories that tested the same cigarette brand styles. From these

results, a test was performed to see if the set of models fit for different laboratories smoking the same brand styles provided a statistically significant improvement over a single model fit to data from those laboratories (regardless of smoking machine). The extent to which this test becomes less significant (i.e., laboratories are more alike) as the level of adjustment increases (observed values to All-Adjusted to Regime-Adjusted) provides an indication of the effectiveness of the adjustment.

Finally, similar models were fitted to predict yields when smoking with Regimes #2 and #3 from yields under Regime #1, combining data from all laboratories. From these results, a test was performed to see if the set of models fit for different groups of cigarette brand styles provided a statistically significant improvement over a single model fit to data from all laboratories. These models were fitted and tests performed for laboratory means observed and using both methods of adjustment.

Discussion of Results.

Establish Viability of Participating Laboratories. The Phase 2 study results (mean values obtained in each laboratory) are summarized in Appendix 6.

Results from Dixon tests for normal distribution extreme outlier **replicate values** that were performed on individual linear smoking machine values for each cigarette measured at each smoking regime demonstrate the general viability of laboratories that used linear smoking machines. Across the thirteen cigarettes smoked with three different smoking regimes to yield six analytical endpoints (i.e., puff count; TPM, nicotine, water, NFDPM and CO yields), 2,575 total test sample values were produced by the eleven laboratories with linear smoking machines. Seventy-four values (2.9% of the total data) were identified as outliers. After careful examination, it was decided that removal of these outliers would have minimal impact on the reported mean values and none of these data were excluded.

Similarly, Dixon tests for normal distribution extreme outlier laboratory **means** performed on laboratory means for all laboratories for the three control cigarettes (a commercial 1 mg yield cigarette, the 1R4F Kentucky reference cigarette and CORESTA monitor cigarette CM4) demonstrate the general viability of all laboratories participating in the Phase 2 study. Only one outlier ($p < 0.01$) was identified in the 216 tests conducted (6 endpoints for each of 4 smoking machines for 3 cigarettes at 3 regimens), indicating a very high level of consistency of results among laboratories using the same type of smoking machines (Appendix 7, Table 1). With such minimal impact, no data were excluded as statistical outliers.

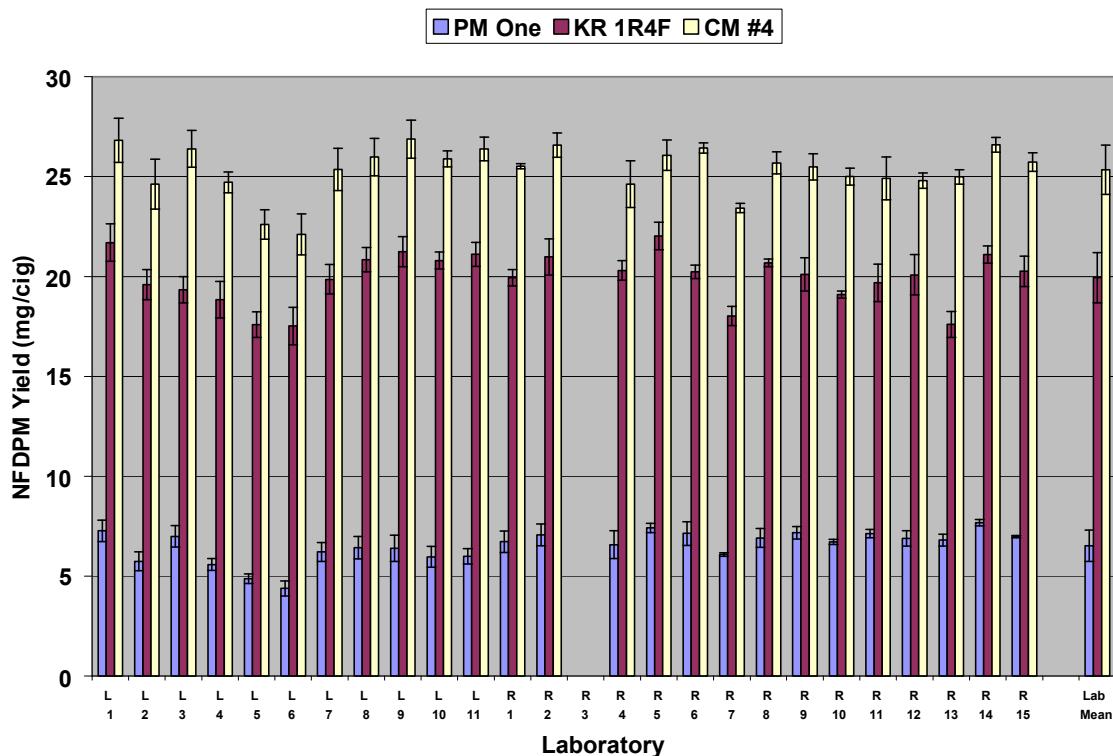

Results for Laboratory L2, products D and J, and for Laboratory R6, product J were excluded when establishing correlation models. Results for product D were excluded because an incorrect product was tested. Results for product J were excluded because it was a reference cigarette, rather than a commercially available cigarette brand. No other results were excluded for an assignable cause.

Evaluate Accuracy. Comparisons of reference cigarette yields obtained in the Phase 2 study with yield values determined historically and in the Phase 1 study provide an indication that general accuracy was achieved by Phase 2 study participants (Table 14). Further inspection of control cigarette data on an individual laboratory basis (e.g., Figure 5) suggests that smoke yields did vary from one laboratory to the next and, in some cases, significantly so (e.g., Laboratory L6 vs. Laboratory R2). Differences in smoking machine type contributed significantly to observed interlaboratory differences (Appendix 7, Tables 14 – 16).

Table 14. Comparison of Historical, Phase 1 and Phase 2 Study Results – 1R4F

Figure 5. Phase 2 Study Control Cigarette NFDPM Yields – Regime #2

(Note: One of the ASR task force participating laboratories (R3) was unable to provide yield data. However, the laboratory designation as defined in the study protocol was retained in the chart).

Since individual laboratory biases potentially confound the ability to accurately develop correlation models for smoke yields between ISO and representative alternative smoking regimes (the principal task force objective), adjustments to the data based on control cigarette yield values were investigated. By design, testing of control cigarettes with each product group provides a means of correcting for interlaboratory biases in much the same way as an internal standard corrects for injection volume variation in gas chromatography. Adjustments to correct for observed interlaboratory biases are particularly pertinent for the Phase 2 study design, because individual product groups are tested in only 2 – 4 laboratories. Such adjustments are intended to eliminate potential biases in individual data sets due to smoking machine type or other unique laboratory factors, such that the true smoke yield relationship between smoking regimes may be best discerned.

For this purpose, models relating the yields of the three control cigarettes at each laboratory to the grand means observed for all laboratories were fitted. Models were fitted both for yields of the control cigarettes for all three smoking regimes combined (e.g., Figure 6) and for each smoking regime separately. Differences in slope and intercept coefficients were observed for the different model types and for the individual smoking regimes in some instances (Table 15). Tests were performed to determine if the

set of control cigarette models fit separately for each regime provided statistically significant improvement in the fit (i.e., a significant reduction of unexplained variation) compared to a single model fit for all three regimes combined. Statistically significant improvements in the fit were observed for several laboratories when control cigarette yield models were fitted separately for each smoking regime (Appendix 7, Tables 2 – 4). For example, significantly improved control cigarette yield models for three of the four laboratories summarized in Table 15 (Laboratories L5, L6 and R14) were found with individual regime models. As such, adjustment models based on all smoking regimes and individual regimes were applied to all observed smoke yields (Appendix 7, Tables 5 – 7) prior to developing correlation models for smoke yields between ISO and representative alternative smoking regimes. For each endpoint, means observed at each laboratory were adjusted by subtracting the intercept and dividing by the slope of the model fit for that laboratory. This adjusted value is the grand mean that would have been produced if each product had been tested in all participating laboratories, and thus has the effect of removing laboratory differences.

Regime 3	1.0286	0.5887	1.0000

Evaluate Precision. Means, repeatability standard deviation and reproducibility standard deviation estimates to describe the test method capability for each type of smoking machine based on the three control cigarettes common to all laboratories in the Phase 2 study are summarized in Appendix 7, Tables 11 – 13. The variability among replicates run under controlled conditions in the same laboratory (s_i) and the variability among replicates run at different laboratories (s_R) were comparable for Phase 1 and Phase 2 control cigarette NFDPM, nicotine and CO measurements. While differences in both repeatability and reproducibility were observed between the two studies, trends suggesting a consistent increase or decrease from Phase 1 to Phase 2 were not observed. Comparison of Phase 2 study repeatability standard deviation and reproducibility standard deviation estimates to the Phase 1 functional relationships that relate repeatability and reproducibility standard deviations to the sample mean level when combining results from all smoking regimes and for all Phase 1 test products also demonstrate comparable analysis precision for the two studies (Appendix 7, Figures 1 –

30). One notable difference between the two studies concerns the reproducibility standard deviation for the ASM 500 smoking machine, which was generally greater in the Phase 2 study than in the Phase 1 study.

Develop Correlation Models. In order to develop correlation models for “tar”, nicotine and CO between the ISO and representative alternative smoking regimes, two factors were first considered: (a) the effect of potential adjustments to the originally observed data based on control cigarette yields and (b) the scope of the cigarette brands styles included as the basis for establishing functional relationships. A discussion of each of these concepts follows.

Potential Adjustments to the Data. Phase 2 study data were evaluated with and without adjustment to the data based on observed control cigarette yields. Correlation models for smoke yields between ISO and representative alternative smoking regimes were evaluated: (1) with no adjustment to the data, (2) with adjustment based on control cigarette yields at all three smoking regimes simultaneously (“All-Regimes-Adjusted”) and (3) with adjustment based on control product yields at each individual smoking regime (“Regime-Adjusted”) for the specific laboratory.

Adjustments based on the control cigarettes did eliminate potential interlaboratory biases caused by smoking machine type or other unique laboratory factors, with Regime-Adjusted data eliminating the greatest extent of bias. This effect is illustrated for the European brands group in Figures 7 – 9 (Regime 2 NFDPM yields) and Figures 10 – 12 (Regime #3 NFDPM yields). Significant differences are observed in the functional relationships found for the individual laboratories testing the European brands group when the data are evaluated without adjustment (Figures 7 and 10). While the All-Regimes Adjusted data eliminates some of the biases observed between the laboratories, the Regime-Adjusted data eliminates the greatest extent. With Regime-Adjusted data, NFDPM yields for each cigarette tend to cluster together and the most consistent regression results are observed for the four laboratories.

Statistical analysis results for each product group based on observed data, All Regimes-Adjusted data and Regime-Adjusted data are summarized in Appendix 7, Tables 8 – 10. In these tables the “p: multiple lines” statistic tests whether a multi-line model (i.e., lab by lab) reduces the error sum of squares as compared to a single line based on all labs. When $p < 0.05$, a multi-laboratory model significantly improves the fit. If adjustments to the data based on control cigarette yields reduce interlaboratory biases, then fewer incidences of $p < 0.05$ should be observed when adjustment is applied. This is the case, with the fewest incidences of $p < 0.05$ observed for Regime-Adjusted data.

The overall effect from data adjustment is evident from functional relationships based on all products tested in all product groups (Figures 13 – 18), with the least amount of variability in the data and the greatest R^2 values observed for Regime-Adjusted data. As such, functional relationship examples summarized in the tables below reflect Regime-Adjusted data.

Cigarette Brand Styles Used to Establish Functional Relationships. After adjustment for potential laboratory biases, Phase 2 study data were evaluated in a number of ways. First, correlation models for ‘tar’, nicotine and CO smoke yields between ISO and representative alternative smoking regimes (“Massachusetts” and Canadian “Intense”) were compared using a linear model. Tables 16 - 18 summarizes the “global” models (i.e., in each case, a single, grand model for the ~ 90 cigarette brand styles tested from around the world) obtained for NFDPM, nicotine and CO. “Stronger” correlations with the ISO smoking regime were generally observed for Regime #2 than for Regime #3. “Stronger” correlations were also generally observed for ‘tar’ and nicotine than for CO.

Regime #2	~ 7	~ 29	
Regime #3	~ 10	~ 30	

The quality of the functional relationships when results for all brands studied serve as the basis for regression analysis can be assessed by comparing yield values predicted from the functional relationships with measured yield values (Figures 19 – 22). Findings from such a comparison include:

1. A difference of 3 mg, or less, is observed between Regime #2 NFDPM yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
2. A difference of 3 mg, or less, is observed between Regime #3 NFDPM yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. A difference of 5 mg, or less, was observed for more than 90% of the brands tested.
3. A difference of 0.3 mg, or less, is observed between Regime #2 nicotine yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
4. A difference of 0.3 mg, or less, is observed between Regime #3 nicotine yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. A difference of 0.5 mg, or less, was observed for more than 90% of the brands tested.
5. A difference of 3 mg, or less, is observed between Regime #2 CO yields predicted from Regime #1 yields and measured Regime #2 yields for more than 90% of the brands tested.
6. A difference of 3 mg, or less, is observed between Regime #3 NFDPM yields predicted from Regime #1 yields and measured Regime #3 yields for approximately 75% of the brands tested. Further, a difference of 6 – 12 mg is observed for approximately 10% of the brands tested.

Figure 19. Difference between Phase 2 Study Measured and Predicted NFDPM Values

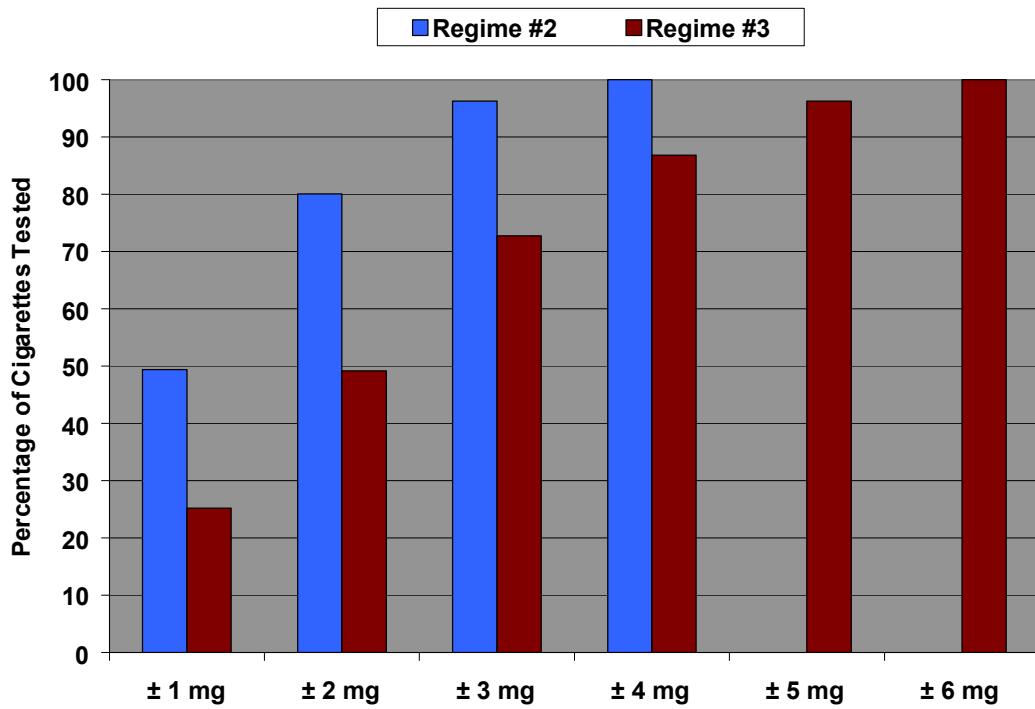

Figure 20. Difference between Phase 2 Study Measured and Predicted Nicotine Values

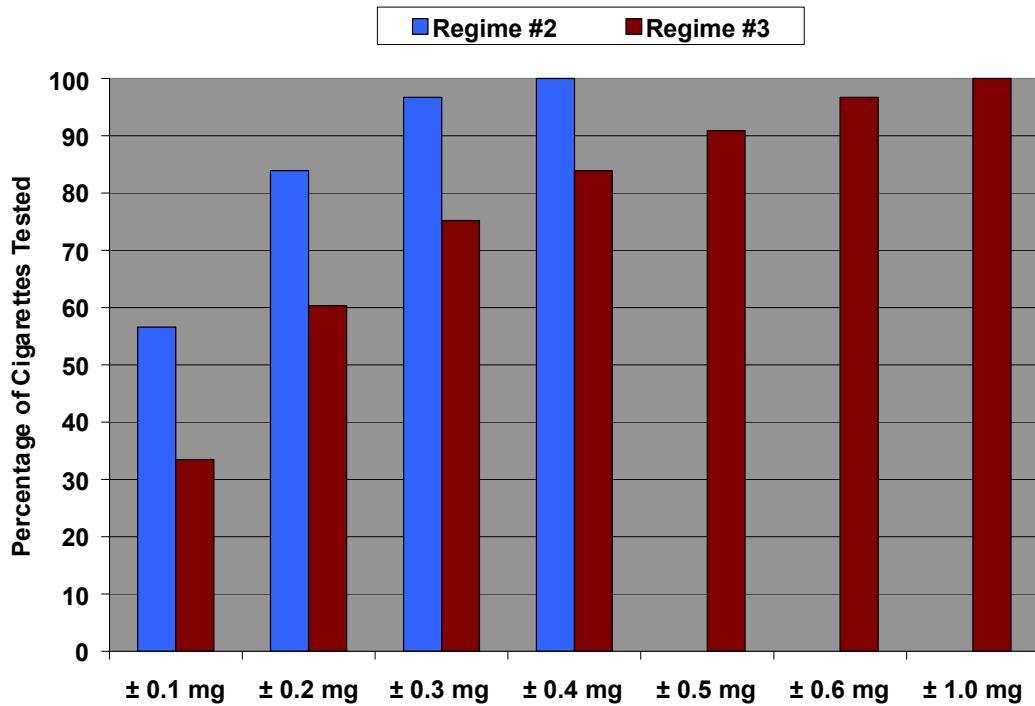

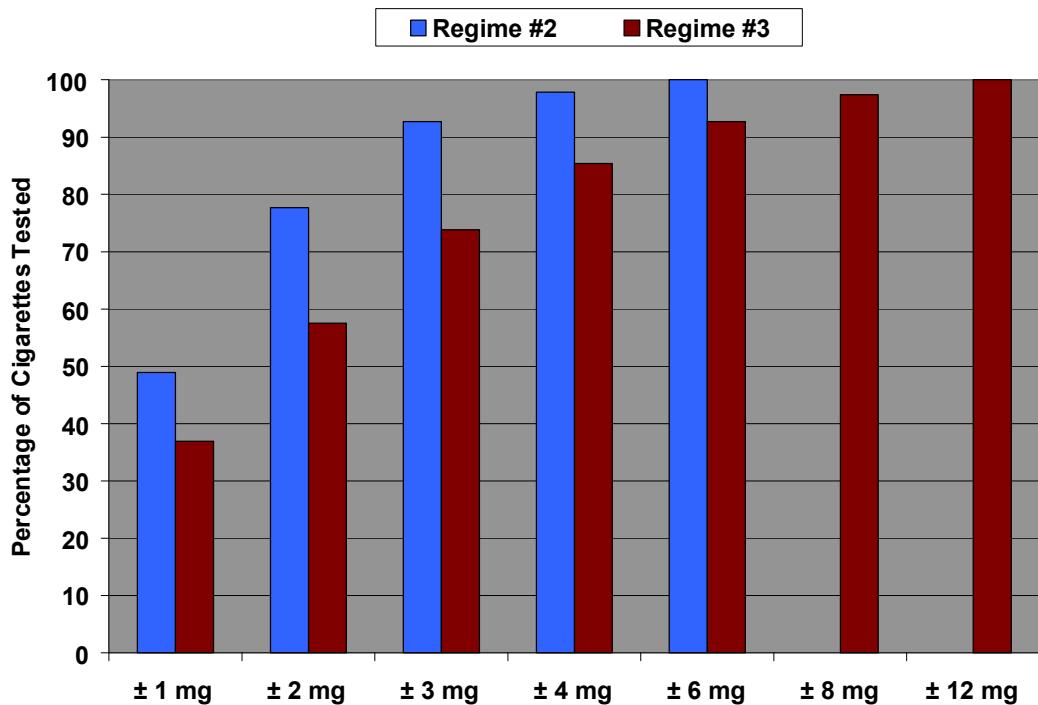

Figure 21. Difference between Phase 2 Study Measured and Predicted CO Values

Inspection of the Phase 2 study data by tobacco blend type (e.g., Figures 22 – 23) suggests that correlation models between ISO and alternative smoking regimes based on blend type may describe the data better than a single, grand model. Statistical analysis results (Appendix 7, Table 17) confirm that significant additional variation in the data is explained by individual blend group models compared to a single grand model inclusive of all cigarettes tested. Significant improvements are observed for all smoke yields (NFDPM, nicotine and CO). Correlation models based on blend type are summarized in Tables 19 – 24).

When correlation models are explored based on tobacco blend: (a) distinct functional relationships between ISO (Regime #1) nicotine and Regime #2 or Regime #3 nicotine were observed for some blends, (b) a tendency toward distinct slopes and intercepts (i.e., functional relationships) between ISO (Regime #1) NFDPM and Regime #2 or Regime #3 NFDPM were observed for some blends and (c) similar functional relationships between ISO (Regime #1) CO and either Regime #2 or Regime #3 CO were observed for different blends.

Similarly, inspection of Phase 2 study data by product group suggests that correlation models between ISO and alternative smoking regimes based on individual product groups may describe the data better than a single, grand model. Statistical analysis results (Appendix 7, Table 18) confirm that significant additional variation in the data is explained by individual product group models compared to a single grand model fit to all

cigarettes tested. Significant improvements are observed for all smoke yields (NFDPM, nicotine and CO). Correlation models based on blend type are summarized in Tables 25 – 30). When correlation models are explored by product group, distinct slope and intercept values are found for a number of product group NFDPM, nicotine and CO models.

Conclusion from Phase 2 Study. The Phase 2 study was successful in generalizing the results from the Phase 1 study, by expanding the breadth of cigarette designs studied. A comprehensive study applying alternative smoking regimes to approximately ninety cigarette brand styles from various regions of the world, with numerous designs and a variety of tobacco blends has been completed, broadening the scope of cigarette products evaluated in the first phase of the ASR task force work.

The ‘tar’, nicotine and CO yield data obtained from the study provide the basis for correlation models between ISO smoke yields and representative alternative smoking regime smoke yields, when such correlations exist. When correlation models between ISO and representative alternative smoking regimes were compared for the brands studied, “stronger” correlations were generally observed for Regime #2 than for Regime #3. “Stronger” correlations were generally observed for ‘tar’ and nicotine than for CO (An “adequate” functional relationship was not observed between ISO (Regime #1) CO yields and Regime #3 CO yields based on the cigarettes studied). Also, blend specific models improved the quality of the correlation models, as did models based on specific product groups.

Appendix 2. Phase 1 Study Protocol

Test Protocol for the CORESTA Alternative Puffing Regime Task Force – Phase 1 Collaborative Study

1. Schedule

- Each supplier laboratory of test cigarettes shall ship two cartons of the same batch of test cigarettes to each participating laboratory by March 15, 2001. (Note: All participating laboratories will be responsible for purchasing CORESTA monitor cigarette CM3 for their own use. The supplier laboratories will provide all other cigarettes.)
- Cases and cartons shall be unpacked, and packages containing test cigarettes shall be mixed and sampled at random in each participating laboratory.
- Laboratories shall determine NFDPM, nicotine and CO in mainstream smoke of test cigarettes using three separate smoking regimes during March, April and early May 2001.
- All available test results shall be reported to Mike Borgerding, Steve Chapman and Yves St. Jalm by May 14, 2001.
- M. F. Borgerding and P. Case will compile test results and a preliminary analysis of data from the study will be reported to all participating laboratories at the Task Force Meeting scheduled for May 30, 2001.
- Next Task Force Meeting will be held on May 30, 2001 in Paris, France at the invitation of ALTADIS. The details will be decided by ALTADIS and each participating laboratory will be notified with an invitation letter.

2. Test Cigarettes

As shown in Table 1, ten (10) commercial test cigarettes different in "tar" (NFDPM) level and two reference cigarettes shall be used in the collaborative study.

Table 1. Test Cigarettes for Phase 1 Collaborative Study

Sample code	Sample name (Supplier)	NFDPM level (mg/cig.)	Butt length (mm)	Circumference (mm)
A	State Express	12	29	24.7
B	Marlboro KS	12	29	24.8
C	Gauloises Filtre	10	22	26.7
D	Camel Medium	9	35	24.9
E	B&H	8	29	24.7
F	Davidoff Light	7	33	24.8
G	Camel Light	6	35	24.9
H	R6 KS	4	33	24.8
I	Marlboro Ultra Light 100	3	39	24.6
J	Philip Morris One KS	1	35	24.8
K	Kentucky Reference Cig. 1R4F	9	35	
L	CORESTA Approved Monitor CM3	15~16	32	

3. Test Method

The CORESTA Alternative Puffing Regime Task Force – Phase 1 Collaborative Study shall be conducted in accordance with the ISO standards noted below. For smoking regimes other than the standard ISO regime, regulatory documents and/or analytical methods from Massachusetts and Canada, in addition to individual corporate analysis methods applied in the 1999 Massachusetts Benchmark Study, are provided for guidance.

ISO Standards (smoking regime: 35/60/2 w 0% VB)

ISO 3402 Tobacco and tobacco products - Atmosphere for conditioning and testing (4th edition, 1999-12-15)

ISO 3308 Routine analytical cigarette-smoking machine - Definitions and conditions (4th edition, 2000-04-15)

ISO 4387 Cigarettes - Determination of total and nicotine-free dry particulate matter using a routine analytical smoking machine (3rd edition, 2000-04-01)

ISO 10315 Cigarettes - Determination of nicotine in smoke condensates - Gas-chromatographic method (2nd edition, 2000-04-01)

ISO 10362-1 Cigarettes - Determination of water in smoke condensates - Part 1: Gas-chromatographic method (2nd edition, 1999-12-15)

ISO 8454 Cigarettes – Determination of carbon monoxide in the vapour phase of cigarette smoke – NDIR method (2nd edition, 1995-11-15)

Massachusetts Guidelines (smoking regime: 45/30/2 w 50% VB)

<http://www.state.ma.us/dph/mtcp/report/ingreg.htm#purpose>

Massachusetts Nicotine Reporting Regulation. 105 CMR: Department of Public Health 105 CMR 660.000 Cigarette and Smokeless Tobacco Products: Reports of Added Constituents and Nicotine Ratings 660.102: Cigarette Nicotine Yield Rating Reporting Requirements

Laboratory Test Methods Applied in the 1999 Massachusetts Benchmark Study (see attachments):

- **Brown & Williamson Tobacco Corporation – “Modified FTC Method for the Determination of Total Particulate Matter, Puff Number, Carbon Monoxide, Nicotine and “Tar” in Mainstream Smoke”**
- **Lorillard Tobacco Company – “Specifications for the Collection of Mainstream Smoke”**
- **Philip Morris USA – “Analysis of Mainstream Smoke for Nicotine and Water”**
- **R. J. Reynolds Tobacco Company – ‘Determination of “Tar,” Nicotine and Carbon Monoxide in Mainstream Smoke’**

Canadian Intense Guidelines (smoking regime: 55/30/2 w 100% VB)

<http://www.hc-sc.gc.ca/hppb/tobacco/ehd/tobacco/testmethods/pdf/Methods/100PDF-english/T-115e4.PDF> Health Canada ‘Official Method T-115, Determination of “Tar”, Nicotine and Carbon Monoxide in Mainstream Tobacco Smoke’ under conditions set out in section 14. (6) (b) (i.e. “Modified conditions”) of the current Canadian Federal Tobacco Reporting Regulations.

General Test Method Guidelines

As a general guide, experiments conducted under each puffing regime should be conducted according to ISO standard requirements. Exceptions to this guiding principle include the puffing parameters applied for the different smoking regimes, the cigarette vent blocking condition applied and the number of cigarettes smoked per sample. Please note that any operating conditions (a) not specified in the above ISO standards, or regarded as optional, (b) not specified in the Massachusetts or Canadian “methods” provided as guidelines and (c) any circumstances that may have influenced test results shall be noted in the test report.

Puffing parameter and vent blocking specifications for each puffing regime are summarized in Table 2. Figure 1 provides an example of vent blocking.

When vent blocking cigarettes, tape shall be applied from the tipping joint to the mouth end of the cigarette. For smoking regime #2 (pictured in Figure 1), 50% of the cigarette circumference shall be blocked with tape. Typically, this is accomplished by selecting tape of a width that corresponds to $50\% \pm 1\%$ of the cigarette circumference, applying the tape from the tipping joint to extend beyond the mouth end of the cigarette, rolling the tape around the filter circumference and then trimming at excess tape at the mouth end with scissors to complete the process. Three rolls of tape (each of a different width) will be provided to participating laboratories. Choice of tape for smoking regime #2 should be based on ranges found in Table 3.

Table 2. Smoking Regime Specifications

Smoking Regime	Puff Volume (cc)	Puff Frequency* (s)	Puff Duration (s)	Vent Blocking (%)	Description
1	35 ± 0.3	60 ± 0.5	2 ± 0.2	0	ISO Standard
2	45 ± 0.5	30 ± 1	2 ± 0.2	50 ± 1	Massachusetts "Average"
3	55 ± 0.5	30 ± 1	2 ± 0.2	100	Canada "Intense"
* Time from the start of one puff to the start of the next puff.					

Figure 1. Example of 50% Vent Blocking

Table 3. Choice of Tape Width for 50% Vent Blocking (Regime #2)

Tape Width Provided (mm)	Applicable to Cigarette Circumference Range (mm)
12.2	23.9 – 24.9
12.7	25.0 – 25.9
13.5	26.5 – 27.5

Major points to which special attention should be paid are as follows:

(1) Sampling, Conditioning and Selection of Test Cigarettes

- For each cigarette brand received, a composite of all packs shall be prepared for conditioning. If a substantial period of time is expected to occur between the times when cigarettes are smoked with the different smoking regimes, then three separate composite samples shall be prepared, one for each smoking regime.
- Test cigarettes sampled shall be conditioned more than 48 hours but less than 10 days under the following conditions.

Temperature: $22 \pm 1^{\circ}\text{C}$

Relative humidity: $60 \pm 3\%$

Temperature and relative humidity of the conditioning enclosure shall be checked and recorded for every smoking run.

- Test cigarettes to be smoked for the determination of NFDPM, nicotine and CO shall be selected at random from the conditioned cigarettes. Any cigarettes with visible defects (e.g. air leak, badly filled, etc.) shall be discarded.

(2) Smoking Machine

A linear type smoking machine or a rotary type smoking machine shall be used, if available. If an automatic RM200 rotary smoking machine is used, the new modification kit proposed by Borgwaldt should be used when available. Report the presence or not of this modification kit.

(3) Number of Cigarettes Smoked

For smoking regime #1, either fifty (50) cigarettes or sixty (60) cigarettes shall be smoked for each test cigarette brand (depending upon smoking machine type) according to the smoking plan shown in Table 4 or 5.

For a linear type smoking machine, 5 cigarettes shall be smoked per smoke trap.

For a rotary type smoking machine, 20 cigarettes shall be smoked per smoke trap.

For smoking regimes #2 and #3, thirty (30) cigarettes shall be smoked for each test cigarette brand according to the smoking plan shown in Table 4 or 5.

For a linear type smoking machine, 3 cigarettes shall be smoked per smoke trap.

For a rotary type smoking machine, 10 cigarettes shall be smoked per smoke trap.

(4) Smoking Plan

Table 4. Smoking plan for a 20-port linear type smoking machine

Day	Run No.	Smoking Port																			
		1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
1	1	A	B	C	D	E	F	G	H	I	J	K	L	A	B	C	D	E	F	G	H
	2	I	J	K	L	A	B	C	D	E	F	G	H	I	J	K	L	A	B	C	D
2	3	E	F	G	H	I	J	K	L	A	B	C	D	E	F	G	H	I	J	K	L
	4	B	C	D	E	F	G	H	I	J	K	L	A	B	C	D	E	F	G	H	I
3	5	J	K	L	A	B	C	D	E	F	G	H	I	J	K	L	A	B	C	D	E
	6	F	G	H	I	J	K	L	A	B	C	D	E	F	G	H	I	J	K	L	A

Table 5. Smoking plan for a rotary type smoking machine

Run	Sample								
No.	code								
1	A	9	I	17	F	25	C	33	K
2	B	10	J	18	G	26	D	34	L
3	C	11	K	19	H	27	E	35	A
4	D	12	L	20	I	28	F	36	B
5	E	13	B	21	J	29	G		
6	F	14	C	22	K	30	H		
7	G	15	D	23	L	31	I		
8	H	16	E	24	A	32	J		

(5) Cigarette Holder and Smoke Trap

Cigarette holder and smoke trap (filter assembly) defined by ISO 3308 shall be used.

(6) Butt Length

The butt length of each sample according to ISO 4387 is shown in Table 1.

(7) Air Velocity at the Cigarette Level

The mean air velocity at the reference position (see ISO 3308) shall lie in the range 200 ± 30 mm/sec, with air velocity at each individual port in the range 200 ± 50 mm/sec.

Air velocity should be checked, and adjusted within the above velocity if necessary, at least daily and recorded.

(8) Smoking Conditions

- Ambient conditions
 - Temperature $22 \pm 2^{\circ}\text{C}$
 - Relative humidity $60 \pm 5\%$
- Puff volume As specified in Table 2
- Puff duration As specified in Table 2
- Puff frequency As specified in Table 2

Temperature, relative humidity and atmospheric pressure (if determine CO) of the smoking environment shall be checked and recorded for every smoking run.

(9) Determination of TPM

The average amount of total particulate matter, TPM, for each smoke trap expressed in mg/cigarette shall be calculated as the increase in weight of the smoke trap before and after smoking.

Calculate the amount of TPM of each smoke trap in mg/cigarette to two decimals.

(10) Determination of Water and Nicotine

TPM collected on the glass fiber filter shall be dissolved in a solvent, and the water and nicotine content in this solution shall be determined by gas chromatograph in accordance with ISO 10362-1 and 10315, respectively.

Calculate the water and nicotine content in TPM per cigarette in mg to two decimals.

(11) Calculation of Amount of NFDPM (Tar)

The amount of NFDPM for each smoke trap, expressed in mg/cigarette, is given by the equation;

$$\text{NFDPM} = \text{TPM} - \text{N}_i - \text{W}_a,$$

where,

TPM is the amount of TPM expressed in mg/cigarette (two decimals).

N_i is the nicotine content in TPM expressed in mg/cigarette (two decimals).

W_a is the water content in TPM expressed in mg/cigarette (two decimals).

Calculate the amount of NFDPM per cigarette, in mg to two decimals, for each smoke trap according to the above equation.

(12) Determination of CO

CO in the vapour phase of cigarette smoke shall be determined with a non-dispersive infrared (NDIR) analyzer calibrated for CO in accordance with ISO 8454. Calculate the amount of CO per cigarette, in mg to two decimals, for each smoke trap according to ISO 8454.

CO determination is encouraged, but it is optional.

4. Report of Test Results

Test results shall be reported electronically by floppy disk (3.5 inches/Windows/MS Excel) accompanied by printed copies of each

designated form. A floppy disk containing data sheets designated for each report and is enclosed with this protocol. Note: To facilitate rapid communication, electronic templates will also be e-mailed to each participating laboratory when e-mail is available. Also, please e-mail all results to borgerm@rjrt.com (M. F. Borgerding) as data becomes available.

5. Notes for the CORESTA Alternative Puffing Regime Task Force – Phase 1 Collaborative Study

1. The study is considered a preliminary study.
2. A pre-test will be conducted for each smoking regime after smoking machines are adjusted to specifications for Regime #2 and Regime #3. It is recommended for linear smoking machines that ten ports of Kentucky reference cigarette 1R4F be smoked. It is recommended for rotary smoking machines that three samples of Kentucky reference cigarette 1R4F be smoked. When the preliminary experiment is completed, please e-mail all data to M. F. Borgerding (at borgerm@rjrt.com). Results from the pre-test will be shared with all participating laboratories, as they become available, to serve as a resource during the implementation phase of the study. Historical values obtained when smoking the 1R4F cigarette with Regime #2 and Regime #3 are summarized in Table 6. Regime #2 data are based on the determination of eighty ports worth of data (twenty ports per laboratory; four laboratories) from a “single composite” batch of product. Regime #3 data are based on results from a fifth laboratory over a two year period.

Table 6. Historical 1R4F Results

	Regime #2 (45/30/2 w 50% VB) Average \pm 1 SD	Regime #3 (55/30/2 w 100% VB) Average \pm 1 SD
“Tar” (mg/cig)	20.4 ± 0.9	29.7 ± 1.8
Nicotine (mg/cig)	1.60 ± 0.07	1.87 ± 0.11
CO (mg/cig)	24.7 ± 1.4	30.9 ± 2.0

3. Choice of the number of cigarettes smoked per smoke trap for each smoking regime applied in study and the number of replicate determinations mandated are based upon several factors, including: (a) available data regarding individual smoke trap collection capacity, (b) consideration of linear and rotary smoking machine design characteristics, (c) the fact that the fundamental purpose of the study is to compare aggregate results from multiple laboratories and cigarette types to evaluate the effect of different smoking regimes on smoke yields and (d) an attempt to maintain consistency when possible for different smoking machine types within a single smoking regime, as well as, consistency across smoking regimes for a single smoking machine type. These scientific considerations were also balanced against the practical consideration of a large study scope, i.e., three smoking regimes and twelve cigarette types in the study.

Appendix 4, Table 1. Phase 1 Study Outliers Based on Preliminary Mandel Plots

Original Data												
No.	Lab #	Lab	Cig	Regimen	Rep	TPM (mg/cig.)	Water (mg/cig.)	Nicotine (mg/cig.)	NFDPM (mg/cig.)	CO (mg/cig.)	Puff Count	Description
1	1	ETI	K	2	8	23.13	3.07	2.40	17.66	24.32	11.70	2.4 Nicotine outlier, drop port
2	2	IMP	B	3	2	46.95	13.67	2.13	31.15	21.70	11.25	21.7 CO outlier - drop port
3	14	JT	A	3	3	36.27	10.37	1.35	24.55	27.60	10.05	1.35 Nicotine outlier, drop port
4	17	BAT	B	1	8	11.80	1.22	0.89	9.69	11.07	7.70	9.69 NFDPM outlier, drop port
5	17	BAT	D	2	10	21.50	4.26	1.62	15.62	18.87	11.13	15.62 NFDPM outlier, drop port
6	17	BAT	F	3	7	39.73	12.65	4.65	22.43	27.31	9.40	Correct nicotine (4.65/3) and NFDPM (was 22.43), replaced with correct value after dividing by number of cigarettes smoked
7	17	BAT	F	3	8	40.57	11.63	4.65	24.29	27.72	9.50	Correct nicotine (4.65/3) and NFDPM (was 24.29), replaced with correct value after dividing by number of cigarettes smoked
8	17	BAT	H	2	4	17.10	1.58	3.30	12.22	16.61	12.30	Correct nicotine (3.30/3) and NFDPM (was 12.22), replaced with correct value after dividing by number of cigarettes smoked
9	17	BAT	L	2	4	28.20	4.93	1.57	21.70	20.63	13.03	1.57 nicotine outlier, 21.7 NFDPM outlier, drop port
10	18	GAL	B	3	6	49.33	27.98	2.06	19.29	17.14	11.70	19.29 NFDPM outlier, drop port
11	18	GAL	G	2	7	21.30	4.13	1.23	21.30	21.37	11.50	21.3 NFDPM calc error, but 21.37 CO outlier, drop port
12	21	RBH	B	2	6	22.00	6.10	0.82	15.08	25.78	12.60	Leak, 15.08 NFDPM outlier, drop port
13	21	RBH	F	2	9	1.90	5.17	1.57	-4.84	22.02	12.20	Weighing Error, drop port
14	21	RBH	G	1	5	5.54	0.45	0.44	4.65	5.39	7.80	0.44 nicotine outlier, drop port

Additional: All Regimen 3 Gallaher CO data is excluded
Arista shows generally higher NFDPM yields, NOT excluded from models initially

Appendix 5. Phase 2 Study Protocol

Test Protocol for the CORESTA Alternative Puffing Regime Task Force – Phase 2 Collaborative Study

1. Schedule

- Each supplier laboratory of test cigarettes shall ship two cartons of the same batch of test cigarettes to selected participating laboratories as set out in Appendix 1.
- Shipment of all products will be completed by July 15, 2002. (Note: All participating laboratories will be responsible for purchasing CORESTA monitor cigarette CM4 for their own use. PM International will provide two cartons of Philip Morris One KS and R. J. Reynolds Tobacco will provide two cartons of Kentucky Reference Cigarette 1R4F to each participating laboratory. The supplier laboratories will provide all other cigarettes.)
- CORESTA monitor cigarette CM4 can be purchased from:

Borgwaldt Technik
Schnackenburgerallee 15
D-22525 Hamburg, Germany
Tel : + 49 40 85 31 380
Fax : + 49 40 85 05 600
email BT@borgwaldt.de

Cerulean
Rockingham Drive
Linford Wood East
Milton Keynes MK14 6LY, United Kingdom
Att : Vicky Diamond, Customer Service Manager
Tel + 44 1908 396016
Fax + 44 1908 396087
email: vicky.diamond@molins.com

- Cases and cartons shall be unpacked, and packages containing test cigarettes shall be mixed and sampled at random in each participating laboratory.
- Laboratories shall determine NFDPM, nicotine and CO in mainstream smoke of test cigarettes using three separate smoking regimes during August, September and October 2002.
- All test results shall be reported to Steve Chapman, Mike Borgerding and Yves St. Jalm by November 8, 2002.
- M. F. Borgerding and W. T. Morgan will compile test results and a preliminary analysis of data from the study will be reported to all participating laboratories at the Task Force Meeting tentatively scheduled for December 12, 2002 in Paris France.

2. Test Cigarettes

As shown in Tables 1 - 9, groups of ten (10) commercial test cigarettes different in “tar” (NFDPM) level and three “reference cigarettes” shall be used in the collaborative study.

3. Test Method

The CORESTA Alternative Puffing Regime Task Force – Phase 2 Collaborative Study, consistent with measurements made in the Phase 1 Collaborative Study, shall be conducted in accordance with the ISO standards noted below. For smoking regimes other than the standard ISO regime, regulatory documents and/or analytical methods from Massachusetts and Canada, in addition to individual corporate analysis methods applied in the 1999 Massachusetts Benchmark Study, are provided for guidance.

ISO Standards (smoking regime: 35/60/2 w 0% VB)

ISO 3402 Tobacco and tobacco products - Atmosphere for conditioning and testing (4th edition, 1999-12-15)

ISO 3308 Routine analytical cigarette-smoking machine - Definitions and conditions (4th edition, 2000-04-15)

ISO 4387 Cigarettes - Determination of total and nicotine-free dry particulate matter using a routine analytical smoking machine (3rd edition, 2000-04-01)

ISO 10315 Cigarettes - Determination of nicotine in smoke condensates - Gas-chromatographic method (2nd edition, 2000-04-01)

ISO 10362-1 Cigarettes - Determination of water in smoke condensates - Part 1: Gas-chromatographic method (2nd edition, 1999-12-15)

ISO 8454 Cigarettes – Determination of carbon monoxide in the vapour phase of cigarette smoke – NDIR method (2nd edition, 1995-11-15)

Massachusetts Guidelines (smoking regime: 45/30/2 w 50% VB)

<http://www.state.ma.us/dph/mtcp/report/ingreg.htm#purpose> Massachusetts Nicotine Reporting Regulation. 105 CMR: Department of Public Health 105 CMR 660.000 Cigarette and Smokeless Tobacco Products: Reports of Added Constituents and Nicotine Ratings 660.102: Cigarette Nicotine Yield Rating Reporting Requirements

Laboratory Test Methods Applied in the 1999 Massachusetts Benchmark Study (see attachments):

- Brown & Williamson Tobacco Corporation – “Modified FTC Method for the Determination of Total Particulate Matter, Puff Number, Carbon Monoxide, Nicotine and “Tar” in Mainstream Smoke”
- Lorillard Tobacco Company – “Specifications for the Collection of Mainstream Smoke”
- Philip Morris USA – “Analysis of Mainstream Smoke for Nicotine and Water”
- R. J. Reynolds Tobacco Company – ‘Determination of “Tar,” Nicotine and Carbon Monoxide in Mainstream Smoke’

Canadian Intense Guidelines (smoking regime: 55/30/2 w 100% VB)

<http://www.hc-sc.gc.ca/hppb/tobacco/ehd/tobacco/testmethods/pdf/Methods/100PDF-english/T-115e4.PDF> Health Canada ‘Official Method T-115, Determination of “Tar”, Nicotine and Carbon Monoxide in Mainstream Tobacco Smoke’ under conditions set out in section 14. (6) (b) (i.e. “Modified conditions”) of the current Canadian Federal Tobacco Reporting Regulations.

General Test Method Guidelines

As a general guide, experiments conducted under each puffing regime should be conducted according to ISO standard requirements. Exceptions to this guiding principle include the puffing parameters applied for the different smoking regimes, the cigarette vent blocking condition applied and the number of cigarettes smoked per sample. Please note that any operating conditions (a) not specified in the above ISO standards, or regarded as optional, (b) not specified in the Massachusetts or Canadian “methods” provided as guidelines and (c) any circumstances that may have influenced test results shall be noted in the test report.

Puffing parameter and vent blocking specifications for each puffing regime are summarized in Table 10. Figure 1 provides an example of vent blocking. When vent blocking cigarettes, tape shall be applied from the tipping joint to the mouth end of the cigarette. For smoking regime #2 (pictured in Figure 1), 50% of the cigarette

circumference shall be blocked with tape. Typically, this is accomplished by selecting tape of a width that corresponds to $50\% \pm 1.5\%$ (i.e., 48.5 – 51.5%) of the cigarette circumference, applying the tape from the tipping joint to extend beyond the mouth end of the cigarette, rolling the tape around the filter circumference and then trimming at excess tape at the mouth end with scissors to complete the process. However, for the very few cigarettes with a circumference of 19.2 mm that are in the study, the coverage will be ~55% based on readily available tape widths. Tape rolls of various widths will be provided to participating laboratories. Choice of tape for smoking regime #2 should be based on ranges found in Table 11, as specified in Appendix 2 (i.e., specific tape widths for use are color coded in yellow in the Appendix).

Table 10. Smoking Regime Specifications

Smoking Regime	Puff Volume (cc)	Puff Frequency* (s)	Puff Duration (s)	Vent Blocking (%)	Description
1	35 ± 0.3	60 ± 0.5	2 ± 0.2	0	ISO Standard
2	45 ± 0.5	30 ± 1	2 ± 0.2	50 ± 1	Massachusetts "Average"
3	55 ± 0.5	30 ± 1	2 ± 0.2	100	Canada "Intense"

* Time from the start of one puff to the start of the next puff.

Figure 1. Example of 50% Vent Blocking

Table 11. Choice of Tape Width for 50% Vent Blocking (Regime #2)

Tape Width Provided (mm)	Applicable to Cigarette Circumference Range (mm)
8.5	17.0
10.5	19.2 – 21.4
12.2	23.8 – 24.75
12.7	24.8 – 25.2
13.5	26.7 – 27.1

Major points to which special attention should be paid are as follows:**(1) Sampling, Conditioning and Selection of Test Cigarettes**

- For each cigarette brand received, a composite of all packs shall be prepared for conditioning. If a substantial period of time is expected to occur between the times when cigarettes are smoked with the different smoking regimes, then three separate composite samples shall be prepared, one for each smoking regime.
- Test cigarettes sampled shall be conditioned more than 48 hours but less than 10 days under the following conditions.

Temperature: $22 \pm 1^{\circ}\text{C}$

Relative humidity: $60 \pm 3\%$

Temperature and relative humidity of the conditioning enclosure shall be checked and recorded for every smoking run.

- Test cigarettes to be smoked for the determination of NFDPM, nicotine and CO shall be selected at random from the conditioned cigarettes. Any cigarettes with visible defects (e.g. air leak, badly filled, etc.) shall be discarded.

(2) Smoking Machine

A linear smoking machine or a rotary smoking machine shall be used, as available. If an automatic RM200 rotary smoking machine is used, the new modification kit proposed by Borgwaldt should be used when available. Report the presence or absence of this modification kit.

(3) Number of Cigarettes Smoked

For smoking regime #1, either fifty (50) cigarettes or sixty (60) cigarettes shall be smoked for each test cigarette brand (depending upon smoking machine type) according to the smoking plan shown in Table 12, 13 or 14.

For a linear smoking machine, 5 cigarettes shall be smoked per smoke trap.

For a rotary smoking machine, 20 cigarettes shall be smoked per smoke trap.

For smoking regimes #2 and #3, thirty (30) cigarettes shall be smoked for each test cigarette brand according to the smoking plan shown in Table 12, 13 or 14.

For a linear smoking machine, 3 cigarettes shall be smoked per smoke trap.

For a rotary smoking machine, 10 cigarettes shall be smoked per smoke trap.

(4) Smoking Plan

Table 12. Smoking plan for a 20-port linear smoking machine

4	D	12	L	20	H	28	D	36	L
5	E	13	M	21	I	29	E	37	M
6	F	14	B	22	J	30	F	38	A
7	G	15	C	23	K	31	G	39	B
8	H	16	D	24	L	32	H		

(5) Cigarette Holder and Smoke Trap

Cigarette holder and smoke trap (filter assembly) defined by ISO 3308 shall be used.

(6) Butt Length

The butt length of each sample according to ISO 4387 is shown in Tables 1-9.

(7) Air Velocity at the Cigarette Level

The mean air velocity at the reference position (see ISO 3308) shall lie in the range 200 ± 30 mm/sec, with air velocity at each individual port in the range 200 ± 50 mm/sec. Air velocity should be checked, and adjusted within the above velocity if necessary, at least daily and recorded.

(8) Smoking Conditions

- Ambient conditions

Temperature	22 ± 2 °C
Relative humidity	60 ± 5 %
- Puff volume As specified in Table 10
- Puff duration As specified in Table 10
- Puff frequency As specified in Table 10

Temperature, relative humidity and atmospheric pressure of the smoking environment shall be checked and recorded for every smoking run.

(9) Determination of TPM

The average amount of total particulate matter, TPM, for each smoke trap expressed in mg/cigarette shall be calculated as the increase in weight of the smoke trap before and after smoking. Calculate the amount of TPM of each

smoke trap in mg/cigarette to two decimals.

(10) Determination of Water and Nicotine

TPM collected on the glass fiber filter shall be dissolved in a solvent, and the water and nicotine content in this solution shall be determined by gas chromatograph in accordance with ISO 10362-1 and 10315, respectively. Calculate the water and nicotine content in TPM per cigarette in mg to two decimals.

(11) Calculation of Amount of NFDPM (“Tar”)

The amount of NFDPM for each smoke trap, expressed in mg/cigarette, is given by the equation:

$$\text{NFDPM} = \text{TPM} - \text{N}_i - \text{W}_a,$$

where,

TPM is the amount of TPM expressed in mg/cigarette (two decimals).

N_i is the nicotine content in TPM expressed in mg/cigarette (two decimals).

W_a is the water content in TPM expressed in mg/cigarette (two decimals).

Calculate the amount of NFDPM per cigarette, in mg to two decimals, for each smoke trap according to the above equation.

(12) Determination of CO

CO in the vapour phase of cigarette smoke shall be determined with a non-dispersive infrared (NDIR) analyzer calibrated for CO in accordance with ISO 8454. Calculate the amount of CO per cigarette, in mg to two decimals, for each smoke trap according to ISO 8454. CO determination is encouraged, but it is optional.

4. Report of Test Results

Test results shall be reported electronically by e-mail or, optionally, by CD-R or floppy disk (3.5 inches/Windows/MS Excel). Three Microsoft Excel files designated: “ASR Phase 2 Study_16-port Linear data sheets.xls”, “ASR Phase 2 Study_20-port Linear data sheets.xls” and “ASR Phase 2 Study_20-port Rotary data sheets.xls” will be provided to each study participant via e-mail. **Please do not alter the formats of these files** in any way while entering analysis parameters and results, as this will preclude subsequent application of macro programs to the files. Printed copies of each designated form may accompany electronic reporting, but hard-copy reporting is not required.

Sheet 3R (Regime #3): Rotary Test Results

Data Summary

5. Notes for the CORESTA Alternative Puffing Regime Task Force – Phase 2 Collaborative Study

1. Choice of the number of cigarettes smoked per smoke trap for each smoking regime applied in study and the number of replicate determinations mandated are based upon several factors, including: (a) available data regarding individual smoke trap collection capacity, (b) consideration of linear and rotary smoking machine design characteristics, (c) the fact that the fundamental purpose of the study is to compare aggregate results from multiple laboratories and cigarette types to evaluate the effect of different smoking regimes on smoke yields and (d) an attempt to maintain consistency when possible for different smoking machine types within a single smoking regime, as well as, consistency across smoking

regimes for a single smoking machine type. These scientific considerations were also balanced against the practical consideration of a large study scope, i.e., three smoking regimes and thirteen cigarette types in the study.

**Appendix 6. Summary of Phase 2 Study Results: Mean Values
Obtained in Each Laboratory**

Tables 1 – 9 of Appendix 6 summarize the groups of ten commercial cigarettes and three “reference cigarettes” that constituted each “product group” tested in the Phase 2 portion of the collaborative study. Product groups assigned to each laboratory for testing are indicated in Table 10. Tables 11 – 35 contain Phase 2 study results from each participating laboratory.

* Compares slopes only from Regime 1, 2 and 3. When p <0.05, slopes are statistically significantly different.

** Tests whether a 3-line model (i.e., regime by regime) reduces the error sum of squares as compared to a single line based on all three regimes. When p <0.05, then 3-line model significantly improves the fit.
